Two minor but significant new elements in the texture of historiography during the last part of the nineteenth century may also be mentioned. One lay in the attempt by John Fiske, popularizer of the ideas of Darwin, Huxley and Spencer, to rewrite much American history in evolutionary terms. His numerous works embodied little original research, and his scientific ideas often warped his historical conclusions; but his dashing style and the popular character of his philosophy won many readers. Andrew D. White's *History of the Warfare of Science with Theology in Christendom* (1896) represented to some degree the same impulse. A more fruitful idea for American historians was Frederick Jackson Turner's doctrine of the significance of the frontier in national history, first expounded in 1893. Involving a drastic reinterpretation of the whole course of American cultural and political development, it has been carried into a large number of historical works. A striking general fact in historiography after 1875 was the tendency to turn entirely away from European themes. The one eminent writer to push forward on the path blazed by Prescott and Motley was Henry C. Lea, whose researches on church history bore fruit in a long series of volumes published between 1865 and 1907; among these *Superstition and Force* (1866), *History of the Inquisition of Spain* (1906-07) and *History of Auricular Confession and Indulgences in the Latin Church* (1896) were the most important. Lea's erudite books, written from a Protestant point of view but without controversial character, possessed high literary qualities as well as scientific temper. That America did not produce more writers in such fields was due not only to the lengthening of its own past but also to its expansion westward; the country in far greater degree than in Prescott's day looked inland rather than across the Atlantic.

The close of the nineteenth century and the opening of the twentieth saw an unprecedented number of historical students busy in America, with constantly growing aids in the form of libraries, university seminars, historical organizations and foundations to subsidize research. The American Historical Association was founded in 1884 and the *American Historical Review* in 1895. Scientific principles of study continued to receive emphasis; the tendency to produce monographs and to avoid works of wide scope increased; "literary" qualities were treated coldly; as specialization grew, cooperative histories became numerous; and history reached out to embrace fields previously neglected. In America as in other countries it levied tribute upon archaeology, sociology, economics and psychology. Here and there a striking figure rose above the ranks of smaller men. The principal of these was unquestionably Henry Adams, whose nine-volume *History of the United States of America* (1889-91) is one of the true historical classics of the century. It shows painstaking research, penetrating analysis of both character and political forces and great polish and artistry of narration. In his mastery of the diplomatic background, based on study in foreign archives, Adams set a new mark in American historiography; but his work was deficient on the economic side. Of all American historians he possessed perhaps the greatest powers of intellectual analysis. Because of this intellectual quality his work never gained wide currency. Far more attention was paid to the spirited *History of the United States from the Compromise of 1850* (1893-1906) by James Ford Rhodes, which subordinated military events to political and diplomatic history and was especially notable in its delineation of public opinion. Although he lacked the finer literary qualities Rhodes possessed an instinct for great historic forces, a glowing sympathy for the personages of his story and a breadth of view which made his work absorbing. He wrote for a large public, while other comprehensive historians seemed to write for students. In dealing with the period after the Civil War he failed, however, to bring out the significance of the great capitalistic and agrarian expansion. Among other writers were James Schouler, H. L. Osgood and above all Edward Channing, whose six-volume *History of the United States* (1905-25) resolved the subject into a long and not always well connected series of problems attacked in the fashion of the seminars.

As specialization increased and the field of

history broadened, cooperative histories of a highly scholarly character became important. The first great venture in this field was Justin Winsor's *Narrative and Critical History of America* (8 vols., 1884-89), which was for scholars rather than the general reader or even the average student. It was almost entirely devoted to the period before 1789, and its critical essays on the printed and manuscript sources were its most important feature. Far better proportioned, and adapted to a wider public, was the *American Nation Series*, edited by Albert Bushnell Hart, the first and best cooperative history of the United States on a large scale (28 vols., 1904-18). Its content was primarily political and constitutional, and most volumes were records of fact without much interpretation. More color and narrative interest appeared in the *Chronicles of America* series edited by Allen Johnson (50 vols., 1918-20), which paid greater attention to economic, cultural and military affairs. This was an uneven series, some volumes being excessively popular. A scholarly *History of American Life*, devoted to social and economic factors alone, is in progress under the editorship of Arthur M. Schlesinger and Dixon Ryan Fox (vols. i-iii, vi, viii, xi-xii, 1927-31). Virtually cooperative also were the thirty-nine volumes of Hubert Howe Bancroft's *Works* (1882-90) devoted to the history and anthropology of western America, Mexico and Central America. State history also began to be written cooperatively by scholars, and the *Centennial History of Illinois* (1918-20), a work of five volumes, set a new standard of excellence.

Meanwhile, the influence of seminars grew steadily. Before 1900 that of Herbert Baxter Adams at Johns Hopkins, emphasizing institutional and local history, was especially important; between 1900 and the World War those of William A. Dunning at Columbia on southern reconstruction, of George L. Burr at Cornell on mediaeval history, of C. M. Andrews at Yale on colonial institutions, of Frederick J. Turner at Wisconsin on the frontier and of Morse Stephens at Cornell and California on modern European history proved conspicuously fruitful. More recently special fields have been opened up by the seminars of W. R. Shepherd of Columbia on the expansion of Europe, of Carlton J. H. Hayes of Columbia on nationalism and of C. H. Haskins and Lynn Thorndike, of Harvard and Columbia, on mediaeval science and culture. Another important tendency appeared in the development of regional history. Among the

earliest workers in this field were Clarence W. Alvord and his followers in the middle west, and one result was the establishment of the *Mississippi Valley Historical Review* in 1914. In the southwest important research, extending into the Mexican field, was accomplished at the University of Texas under E. C. Barker and at the University of California under Herbert E. Bolton and Herbert I. Priestley. Southern history remained uncultivated, however, except by individual writers; and it was only in 1928 that a Harvard group established the *New England Quarterly*.

Just before and after the World War, new currents of interest appeared and gave promise of rescuing historical work from excessive specialization. Brisk activity in the field of biography contributed to the invigoration of historical writing. The influence of economic forces upon American history was traced with great verve and with some debt to Marxian ideas in a series of books by Charles A. Beard, of which *An Economic Interpretation of the Constitution* (1913) attracted the most attention. Intellectual history also was treated with a broad sweep by James Harvey Robinson, whose *The Mind in the Making* (1921) reviewed the deposits which various epochs of history had left on the modern mind. Social history for the first time began to be adequately written, while the history of American ideas received adequate presentation in Vernon L. Parrington's *Main Currents in American Thought* (3 vols., 1927-30), a work treating the economic forces, political ideas and cultural trends which had affected American letters from beginning to end. About the same time Sidney B. Fay and Bernadotte Schmitt outstripped European scholars by furnishing the only analyses of the origins of the World War possessing completeness and authority. Books by two non-academic historians, Claude G. Bowers and James Truslow Adams, obtained a vogue recalling the popularity of historical writing in the days of Motley and Prescott. This reemergence of a large public for certain types of history and biography promises to have two healthy results: the direction of attention to important topics rather than petty monographic subjects, and the reintroduction into history of the literary quality which had been so largely driven out by German methods.

S., *The Middle Group of American Historians* (New York 1917); Dunning, W. A., "A Generation of American Historiography" in *American Historical Association, Annual Report, 1917* (Washington 1920) p. 345-54; Griffin, Grace Gardner, *Writings on American History* (1906-), published annually in New York, New Haven and Washington (1908-30); Schlesinger, A. M., *New Viewpoints in American History* (New York 1922); Barnes, Harry Elmer, *The New History* (New York 1925), and "Recent Developments in History" in Ellwood, C. A. and others, *Recent Developments in the Social Sciences* (Philadelphia 1927) ch. vii.

HITZE, FRANZ (1851-1921), German social reformer. Hitze acquired prominence while a student by publishing a collection of addresses on social questions. After his ordination he studied at Rome from 1878 to 1880 and wrote his chief work, *Kapital und Arbeit*, which was

colored by sympathy with the ideas of guild romanticism. In 1880 he became general secretary of the Arbeiterwohl, a Catholic welfare association founded by Franz Brandts, a Gladbach textile manufacturer. Brandts' influence and Hitze's experience in social work in Brandts' factory led him to accept the forms of modern economic life, which he thereafter aimed to modify by social reform. As a member of the Prussian Landtag from 1882 to 1893 and from 1898 to 1912 and of the Reichstag from 1884 to 1921 he was especially interested in progressive labor legislation, on which he had great influence. After the *Februarerlasse* of 1890 Hitze became a leader in the social reform movement, and through the Volksverein für das Katholische Deutschland which he helped found he had great influence in the formation of the German social Catholic movement. From 1893 until 1920 he was professor of Christian social doctrine in the University of Münster. He was also director of the Gesellschaft für Soziale Reform.

By making the Center party a leader in social reform Hitze first succeeded in drawing German Catholics actively into the life of the state, thus upsetting the charge of political and economic inferiority made against them. Whereas Catholics in consequence of the hostility of the modern state to the church and their moral objections to capitalistic principles had formerly shown no confidence in the state and looked to pastoral and charitable work to ameliorate conditions created by capitalism, Hitze at times went so far as to suggest state socialism. His foremost aim was to develop in the workers a feeling of belonging to an adequate estate. Shortly before his death he restated his early corporative ideas, having become convinced that social insurance and protective labor legislation would not alone effect a reasonable reorganization of social and economic life.

FRANZ MÜLLER

Important works: *Die soziale Frage und die Bestrebungen zu ihrer Lösung* (Paderborn 1877); *Kapital und Arbeit* (Paderborn 1881); *Die Arbeiterfrage und die Bestrebungen zu ihrer Lösung* (Berlin 1899, 4th ed. Munich-Gladbach 1905); *Zur Würdigung der deutschen Arbeiter-Sozialpolitik* (Munich-Gladbach 1913); *Geburtenrückgang und Sozialreform* (Munich-Gladbach 1917).

HJÄRNE, HARALD (1848-1922), Swedish historian. Hjärne was professor of history at the University of Uppsala from 1885 until his resignation in 1913. He was an exceptionally learned historian as well as an eminent teacher and almost all the later Swedish historians acknowledged him as their master. As an author Hjärne never concentrated his attention on one great problem and his works were sometimes left uncompleted, yet his scientific productions are most valuable through their multitude of interesting suggestions, ingenious views and splendid characterization of political ideas and personages. Of particular importance were his investigations into the history of eastern Europe, above all into the relations between Sweden and Russia. In the years between 1880 and 1883 he traveled in Russia, Poland, Austria and other countries and afterward published the oldest Swedish-Russian legation documents from the originals in Stockholm and Moscow and wrote several books and papers on the relations between Sweden and eastern Europe. Hjärne devoted his attention also to the older constitutional history of Sweden and to problems of church and state. In his general views on historical matters he agreed with those who regarded the health and strength of the state as the chief factor in the development of nations. An energetic maintenance of inherited institutions in conjunction with moderate reforms calculated to make large circles of the nation responsible in political life was the core of Hjärne's political program. Although Hjärne took an active part in politics and for many years a member of the Swedish Diet he exercised his greatest influence on current affairs by means of his extensive political and historical writing.

HOADLY, BENJAMIN (1676-1761), English theologian. Hoadly, a political cleric, was associated with the leading Whig ministers under Queen Anne, and after the Whig triumph in 1714 was rewarded with three sees.

The revolution settlement of 1688 had involved the decisive rejection of the doctrine of indefeasible hereditary right of the monarchy and the substitution of a monarchy of parliamentary election and control. The naming of new bishops to replace those who refused to take the oath of allegiance to William and Mary provoked a controversy which in the political sphere concerned chiefly the right of the nation to expel the monarch *divino jure* and in the ecclesiastical the authority of the state to deprive of their sees bishops lawfully consecrated. Hoadly was one of the leading clergy who defended both the right of the people to expel a popish ruler and that of the new sovereign to deprive ecclesiastics who refused him allegiance. In a series of popular but ephemeral sermons and in *A Preservative against the Principles and Practices of the Non-jurors both in Church and State* (5th ed. London 1716), his chief political work, he combated the notion of divine hereditary right and rebutted the arguments of the opponents of the revolution. In a sermon on *The Nature of the Kingdom or Church of Christ* (London 1717) he carried his theories further, virtually denying the authority of any visible church to interpret the words of Christ. This reduction of religion to pure individualism provoked the voluminous Bangorian controversy, and Hoadly's latitudinarianism earned him the dislike and opposition of the majority of the clergy. Hoadly was a leading and typical member of the rising school of Whig divines of the early eighteenth century and contributed much to the development of the political and theological doctrines current at that period.

Hearnshaw (London 1928) ch. vi; Laski, H. J., *Political Thought in England from Locke to Bentham* (London 1920); Stephen, Leslie, *History of English Thought in the Eighteenth Century*, 2 vols. (3rd ed. London 1902) vol. ii, p. 152-67.

HOARDING is the storing of wealth by the individual for possible future use or for indefinite possession. It is a primitive form of accumula-

tion and differs from saving in the modern sense of the term in that the latter usually finds its way into the investment field and constitutes in reality a transfer of the use of wealth, while hoarding involves a definite withdrawal of the hoarded object from circulation. Unlike the investor, the hoarder receives no yield from his wealth unless the hoarded commodity appreciates in value. He is also exposed to the risk of theft or fire or must carry the cost of insurance of his hoardings. But he is free from the risks of monetary depreciation, financial panic and business losses which might beset the investor. In general it may be asserted that in times of peace and prosperity the advantage lies with the investor and in times of war or financial panic with the hoarder.

Hoarding is usually confined to durable goods which contain considerable value in small bulk. These may be classed in two categories: the precious metals which serve as a standard of value and are the basis of the medium of exchange; and treasures, such as precious stones, rare paintings, books and similar objects.

The practise of hoarding is probably as old as the institution of property. Its volume and prevalence are in inverse proportion to the degree of economic development, financial organization and business stability. In primitive communities hoarding was prompted by the desire of display and by the enhancement of the social prestige which the possession of wealth confers. Examples of such motives are found in the accumulation of coppers and blankets by the northwest coast Indians of North America and of armlets by the Trobriand islanders off New Guinea and in the treasure keeping of the California Indians. With the introduction of money economy hoarding came to be confined chiefly to coins and precious metals which serve as material for the making of coins. Such hoarding was extensively practised in antiquity, as is evidenced by the safe deposit facilities provided in ancient temples. It was general throughout the Middle Ages and continued well into the modern era. As late as the nineteenth century business men have been known to retire with their fortunes hoarded in the shape of coins and literally to live off their savings. It is said that the bulk of the indemnity paid by France to Germany following the war of 1870-71 was raised from the gold hoards of the French peasants. The widening of investment opportunities, however, the development of sound financial institutions designed to serve the interests of the small saver and the growing sense

of security and confidence in financial and monetary stability have considerably reduced the volume of hoarding in modern times.

Among the great modern nations hoarding is most prevalent in India. Of the world's gold stock India has approximately one fifth, nearly all hoarded. It is estimated that 50 percent of gold coins which find their way into India are melted down and that 75 percent of the gold and 90 percent of the silver bullion are converted into small treasure bars and ornaments and then hoarded. A tremendous amount of precious stones and jewels is hoarded by Indian rulers. It is noteworthy that the Chinese, whose level of economic development approximates that of India, never developed the habit of hoarding. This may be explained partly by the greater stability of the Chinese civilization and partly also by the fact that in the Chinese scale of values scholarship conferred greater prestige than wealth.

In advanced countries the practise of hoarding is resorted to in times of financial panic, monetary disorganization, war and social upheaval. During the World War suspension of specie payments and depreciation of paper currencies in the belligerent countries induced a widespread hoarding of the metal currencies and bullion. Where the value of the paper currency remains unshaken and public distrust is directed against banks and other financial institutions which serve as the depositories of the people's funds, paper currency rather than metal becomes the object of hoarding. This form of hoarding occurs when the depression is accompanied by large bank failures. Effects of such hoarding were felt in the major depressions in modern times and were particularly acute in the United States during the depression which set in in 1929. For the United States it was estimated that the volume of hoarded currency in January, 1932, as measured by the increase in the outstanding volume of currency in circulation, amounted to \$1,300,000,000, or approximately 25 percent of the total money in circulation. How much of this amount constituted genuine hoarding, that is, complete withdrawal from circulation, and how much of this increase was due to other factors, such as reversion to cash payments in communities deprived of banking facilities in the recent wave of bank failures and the holding by banks of larger amounts of cash to insure greater liquidity in times of stress, is difficult to ascertain. Yet the situation seemed serious enough to warrant special antihoarding meas-

ures, such as the issue of Treasury bonds of small denominations and a nation wide educational campaign to point out the effect of hoarding in prolonging the deflationary movement and thus retarding economic recovery. In normal times hoarding is of relatively little significance. It is confined to habitual misers, to inhabitants of undeveloped districts where no adequate banking facilities exist and to immigrant groups who come from economically backward countries and are still animated by the traditional distrust of financial institutions.

The hoarding of money and precious metals which serve as the basis of the medium of exchange and the standard of value restricts the supply of money and credit and at least in theory may bring about or accentuate a falling price level. In practise it is doubtful whether the volume of hoarding is sufficient to bring about measurable disturbances of the price level.

The hoarding of non-currency valuables is of cultural significance; for example, the hoarding of scarce and valuable books, manuscripts, paintings and the like has resulted in the preservation of documents contributing to the knowledge of the development of mankind.

HOBBS, THOMAS (1588-1679), English philosopher. In early life Hobbes acted as an amanuensis to Sir Francis Bacon and was temporary mathematical instructor to Charles II before the Restoration, but he spent most of his life as tutor to the Cavendish earls of Devonshire. In this capacity he traveled through France and Italy and had an opportunity to examine contemporary political institutions. The wars of the *Fronde* in France and the civil war in England constitute the all important historical background to Hobbes' thought. His method of exposition and his materialistic philosophy were largely influenced by the rapid contemporary advances of the mathematical and physical sciences. While

the order in which his principal works appeared was dictated by personal and political exigency, they were intended to have a unity of thought which built up from physics and physiology (*De corpore*) through psychology (*De homine*) to a study of the community (*De cive* and *Leviathan*).

As a materialist and a mechanist Hobbes holds that human conduct is determined by the effect of environmental stimuli operating upon a nature characterized by certain simple qualities, especially the impulse to self-preservation. Self-preservation manifests itself in the two governing masters of human conduct, the fear of pain and the desire for power. Men as such, i.e. in the state of nature, are not governed by considerations of justice or morality, but are deterred from antisocial actions only by fear of punishment. They are, however, naturally guided by reason, which shows them how they may serve their own interest by the acquisition of power and the avoidance of pain. Upon this reason natural law is based. The complete reign of reason, which is a reign of peace and of the absence of immediate fear, is possible only when men have come to recognize the necessity of setting a curb upon immediate egotism and fist right in the interest of more durable gain. Otherwise the life of man must remain "solitary, poor, nasty, brutish and short." A power able to check each in the interest of all must be established. The establishment of this power, dictated by fear of anarchy, is effected among rational men by mutual agreement or contract. The newly born who continue as they grow up to reside in the society thus formed enter into the traditional agreement or original contract. Otherwise they are without social rights. The power established to maintain order and peace is sovereign, omnipotent to impose its will and not subject to private opinions concerning whether its specific actions be reasonable or otherwise, since its establishment with competence to decide disputes is the prime dictate of reason. It may be an individual (i.e. monarchy, which has the advantage of unity of will and avoids the destruction of sovereignty by inner division) or an assembly of men. The sovereign promulgates the law, which determines what is antisocial and what is social and just. Those who are not subject to the sovereign are in a state of nature to it and to those whom it incorporates and whose *persona* it bears. In such a position are all foreign states.

A sovereign which in fact has lost power so far as to be unable to maintain order no longer has a claim to obedience, since it is not actually an

authority. Conversely, de facto authority is also such de jure. No sovereign body may alienate such power as is necessary for government. Doctrines of the division of sovereignty, the subjection of the sovereign to the laws or its restriction in action by the opinion and conscience of individuals are false. Very wealthy men or guilds and corporations with claims to a measure of autonomy, common lawyers who place custom above the living sovereign power, and churches which claim a spiritual allegiance rivaling that of the sovereign are threats to the sovereign, to civic peace and to reason. A sovereign may rightly claim that men should put the rational public conscience before their private conscience. It is, however, irrational for it to demand that a man go to his death or give evidence to incriminate himself, since the very rational basis of the social contract is self-protection. It is moreover irrational for the sovereign to multiply unnecessarily laws and restrictions, since the maximum of freedom consistent with order is desirable; but such laws as it decides to make are just.

This body of theory embraced a system of ethics, psychology, anthropology, education, economics and jurisprudence; but its central position for social science was the monistic theory of sovereignty. Direct and unsparing, Hobbes' thought had during his lifetime more obloquy than influence. After his death the dominance of Locke intensified the unpopularity of Hobbes' theories. But they were revived by the philosophical radicals. James Mill discovered in them a principle for his associationist psychology; Bentham built his utilitarianism on them and Austin his analytical jurisprudence. Hobbes' economic views were in several important respects a distinct departure from the prevailing mercantilism. His emphasis on individualism, on the dormant drive of egoism and self-interest, and his premise of the insatiability of acquisitive wants influenced the later classical school chiefly through their influence on Bentham. His theory of the state as a convenience led him to regard taxation as the price paid for peace and order, and consequently to the benefit theory of taxation and the advocacy of basing taxes on consumption. The most patent charge against Hobbes is the charge of inconsistency, made in his lifetime by Clarendon. Whereas Hobbes is generally although not always concerned to bolster up the Stuarts, his theory justifies the Protectorate when in power and never justifies loyalism beyond the limits of an enlightened self-interest. Hobbes' sovereign

moreover is endowed with qualities of absolute power, which may be the logical consequences of his premises but which are not observable in the practise of governments, even in that of a Louis XIV. It is this in him which has drawn the fire of the pluralists. As Locke points out, social organization and governmental organization are distinguishable and men are not to be deterred from putting restraints upon governments by fear of complete anarchy in society. Here the crudity of Hobbes' psychology is the undoing of his philosophy. The error arises partly from Hobbes' intellectualism, which leads him completely to ignore that herd or family sentiment, later stressed by Filmer, which prevents social disintegration. "Men," says Hobbes, "have no pleasure . . . but a great deal of grief in keeping company." The error is, however, intelligible in an author of the period of the Long Parliament, writing at the height of the triumph of Protestant individualism, and is one congenial to Hobbes' sardonic mind.

Contemporary criticism was centered on Hobbes' egoistic morals and his political defense of absolutism. The retarding influence that his thought exerted upon international law, which traces from his contemporary and rival Grotius, is not patent until later. It results from a defect in Hobbes' logic. If the essential function of the state is to maintain order, then the ancient argument of Dante, reshaped by Kant and expressed in our own day by Hans Kelsen, is cogent that the reign of law must be world wide. By Hobbes' own logic reason dictates an international state: the objections are of a sentimental kind for which Hobbes elsewhere shows no respect. The modern tendency is to sweep away as empty fiction Hobbes' central doctrine of sovereignty. But it seems questionable whether his thesis that in every political community there must be a final arbitral authority ("If two men ride upon a horse one must ride in front") is not still valid and may not lead to conclusions which Hobbes for private and temporary reasons declined to draw.

HOBHOUSE, LEONARD TRELAWNY (1864-1929), English philosopher and sociologist. Hobhouse was educated at Oxford and taught in Merton and Corpus Christi colleges until 1897. From that year until 1902 he was a member of the editorial staff of the *Manchester Guardian*. After acting as secretary of the Free Trade Union for two years he joined the staff of the *Tribune* in London. In 1907 he became professor of sociology in the University of London and remained in that position until his death.

The formative influences upon his work were the synthetic view of philosophy and the evolutionary bias of Spencer, the positivism and humanitarianism of Comte and the social philosophy of Mill and Green. His earliest inquiries were in the domain of logic and epistemology and resulted in an organic view of rationality which was to be the basis of all his future work, and which, although it has affinities with the idealism of Bosanquet, is essentially realistic. He next undertook an elaborate investigation of the growth of mind in the various forms of animal life and of its further evolution in the collective achievements of mankind. His method was to examine and classify the forms of mental activity, social groupings and institutions and to disentangle the principles governing their evolution. These studies led him to formulate a theory of development as consisting in the extension of harmony through a series of syntheses, effected by the liberation of elements originally in conflict and the building up of structures of varying degrees of plasticity, scale and coherence. In his metaphysical work Hobhouse attempted to justify on philosophical grounds a wide application of this theory. He contended that mind is not coextensive with reality but is the principle of orderly growth within it. It is limited by the material it works upon and its purposes themselves undergo development (*Development and Purpose*, London 1913, rev. ed. 1927).

In his sociological works Hobhouse sought by a comparative method to establish a broad correlation between the growth of mind in range and articulateness and the advancing movement of civilization and to provide both a social morphology and criteria for the ethical valuation of the varying phases of social evolution. He inquired into the conditions of social development, arrest and decay, and while careful not to confuse questions of value with questions of fact he sought to bring together the results of his various studies in a final synthesis culminating in a theory of the nature and possibilities of social progress.

The range of Hobhouse's work was encyclopaedic. He was one of the pioneers of comparative psychology; he developed a technique for the handling of the vast and chaotic data of anthropology; he laid the foundations of a scientific sociology; in ethics and social philosophy he gave a penetrating and fruitful restatement of rationalism; and he attempted a synthesis of his scientific and philosophical studies on a scale which must win for him a high place among the systematic thinkers of the world. As a teacher and social leader he inspired love and reverence by the nobility of his thought and utterance, his passion for truth and justice, his wise and tender humanity.

MORRIS GINSBERG

Important works: *The Theory of Knowledge* (London 1896, 3rd ed. 1921); *Mind in Evolution* (London 1901, 3rd ed. 1926); *Morals in Evolution*, 2 vols. (London 1906, 3rd ed. 1915); *Social Evolution and Political Theory* (New York 1911); *Liberalism* (London 1911); *The Metaphysical Theory of the State*, London School of Economics and Political Science, Studies in Economics and Political Science, no. li (London 1918); *The Elements of Social Justice* (London 1922); *The Rational Good* (London 1921); *Social Development* (London 1924).

Consult: Hobson, J. A., and Ginsberg, Morris, *L. T. Hobhouse: His Life and Work* (London 1931); Carter, Hugh, *The Social Theories of L. T. Hobhouse* (Chapel Hill, N. C. 1927); Nicholson, J. A., *Some Aspects of the Philosophy of L. T. Hobhouse*, University of Illinois, Studies in the Social Sciences, vol. xiv, no. iv (Urbana 1928); Barker, Ernest, "Leonard Trelawny Hobhouse" in *British Academy, Proceedings*, vol. xv (1929-30).

HOCK, BARON KARL FERDINAND (1808-69), Austrian public official and economist. Hock studied law and philosophy at the University of Vienna, entered the civil service in 1830 and was for almost forty years closely associated with the financial administration of the country. A free trader, he influenced the economic poli-

cies of Austria not only through his practical work but also through his literary activity. He wrote on a variety of economic topics and was successful in his controversy with Friedrich List over the merits of protection. Hock's contributions to public finance are of lasting value. His study *Die Finanzverwaltung Frankreichs* (Stuttgart 1857) has been adjudged the standard work in its field. Attracted by the problems arising out of the American Civil War and their similarity to those of his own country, such as the conflict between the federal and state powers, he turned to the study of the finances of the United States and published *Die Finanzen und Finanzgeschichte der Vereinigten Staaten von Amerika* (Stuttgart 1867), a work still held in esteem. Hock summed up his vast experience in public finance in the systematic treatise *Die öffentlichen Abgaben und Schulden* (Stuttgart 1863), which contains a skilful elaboration of the modern theory of incidence of taxation and a valuable discussion of the administrative aspects of taxation and the tariff system.

WILHELM GERLOFF

Consult: Hoffinger, in *Allgemeine deutsche Biographie*, vol. xii (Leipsic 1880) p. 530-32.

HODGSKIN, THOMAS (1787-1869), English journalist and social theorist. Hodgskin's contact with Francis Place began shortly after he had been punished for his pamphlet *An Essay on Naval Discipline* (London 1813). Between that time and the appearance of his *Labour Defended against the Claims of Capital* (London 1825) Hodgskin studied economic conditions on the continent, wrote *Travels in the North of Germany* (2 vols., Edinburgh 1820), read widely in economics and philosophy, contributed frequently to well known journals and was an ardent advocate of labor unions. His editorship with J. Robertson of the *Mechanics' Magazine* and his part in the founding of the London Mechanics' Institute in 1823, where he delivered the lectures later published as *Popular Political Economy* (London 1827), made him a pioneer in the movement for adult education.

Although usually classed as a socialist, Hodgskin's political position was more nearly that of an anarchist. He shared the belief of his friend Herbert Spencer that government should maintain peace and order and otherwise scarcely touch the life of the citizen. He was an individualist to the point of resenting even that infrequent form of government interference, the census inquiry. He believed in self-interest and in

competition and in the natural law that would bring ultimate harmony.

Hodgskin's economic position perhaps warrants his reputation as a socialist. He declared that labor alone produces wealth and is therefore entitled to the whole produce of industry. The inheritance of wealth should not be permitted. He went so far as to assert that knowledge, skill and industry are all that are necessary to produce capital. It follows that he was not much impressed by the growth of rent; in fact, he sharply disagreed with Ricardo's opinion that the landlord's share would eventually absorb most of the national surplus. He declared that it is the capitalist who holds the strategic place in industry; who determines rent, a sum sufficient to equalize profits, and wages, a sum sufficient for the subsistence of the laborer. The capitalist is in justice entitled only to the wage which he earns as an "active contriver," i.e. captain of industry. If the assertion that labor is the only source of wealth and the only just recipient of the produce of industry constitutes a labor theory of value, Hodgskin may be counted as a predecessor of Karl Marx. But it must be noted that he made no serious attempt to measure wealth in terms of labor or to offer proof of his statements. His belief seems to have arisen from the fact that labor is active, the machine and the land passive.

Hodgskin's belief in natural law and harmony made him an optimist; in contrast to Ricardo and Malthus he looked forward both to increasing population and to increasing wealth. The increase of population would, he felt, act as the spur to invention, the chief cause of continued progress.

HOERNES, MORITZ (1852-1917), Austrian historian. Hoernes, professor of prehistoric archaeology at the University of Vienna, was originally a classical archaeologist and philologist but in 1885 turned to research in prehistoric archaeology. His important book *Die Urgeschichte des Menschen nach dem heutigen Stande der Wissenschaft* (Vienna 1892) was a pioneer survey of the results of prehistoric excavations and their

relation to the oldest written accounts. In *Natur und Urgeschichte des Menschen* (2 vols., Vienna 1909) he presented a systematic classification of both the archaeological and ethnographical data on primitive cultures under the subject headings of material, social and intellectual culture, ignoring the concept of *Kulturkreise*. Hoernes considered his most significant work to be the second edition of the *Urgeschichte der bildenden Kunst in Europa* (Vienna 1898; 3rd ed. by O. Menghin, 1925), which in addition to incorporating an extensive collection of source material attempted to generalize on the existence, function and stylistic trends of art. He concluded that plastic art had originally a religious and graphic art a profane character and that three periods of prehistoric art closely correlated with three periods of economic development could be distinguished: primary naturalism with developed hunting; primary geometric art with agriculture; and advanced naturalism characterized by a strongly marked propensity to sumptuous display, as exemplified especially by the arabesque and the animal and plant motif in ornament, with military domination. Hoernes also wrote many scientific works on Bosnia and Herzegovina and edited the *Wissenschaftliche Mitteilungen aus Bosnien und der Herzegovina* (13 vols., Vienna 1893-1916).

HOFFMANN, JOHANN GOTTFRIED (1765-1847), Prussian statistician and administrator. In 1806, while employed in the provincial administration of Königsberg, Hoffmann submitted a comprehensive critique of the statistical reform proposed by Krug, the leading figure in the Prussian statistical bureau which had been established in 1805. At that time official statistics were based on annual returns by local governments and were compiled into a single table which attempted to cover all aspects of social life and ran into hundreds of columns; this table was supplemented by a "population list" based on the civil register kept by the clergy. Hoffmann criticized the unwieldiness and illogical arrangement of the table, the inclusion of

information based on returns from private persons, which he therefore regarded as untrustworthy, and the plan of a name register for the entire population. This critique became a turning point in the history of Prussian statistics; in 1809 in connection with the reform in local administration Hoffmann drew up a plan for a new table, for the reorganization of the central bureau and for a change in the procedure of local agencies gathering the material. The plan was accepted in its main outlines; Hoffmann was appointed chief of the bureau when it was reestablished in 1810 and retained this position until 1844. During this period he strove continually for greater reliability, precision and simplicity in statistical results; since the bureau had no organ for the publication of the results of its work, he brought them to general knowledge in the form of magazine and newspaper articles giving an interpretation of the data in the spirit of political arithmetic. He improved mortality and financial statistics and organized the monthly collection of prices of foodstuffs and other necessities.

Hoffmann was not only the creator of Prussian official statistics; he performed valuable services in many other fields. He was a trusted technical adviser of Hardenberg in the foreign negotiations of 1813 to 1815 and from 1817 to 1821 was a counselor of high rank in the Ministry of Foreign Affairs. An outstanding administrator, he participated in the drafting of important economic enactments. He was responsible for the customs and tax law of 1818 based on free trade ideas; for the class tax of 1820, which may be regarded as an early form of progressive income tax and which remained for decades one of the principal direct taxes in Prussia; and for the industrial law of 1845, which allowed a considerable measure of economic freedom while attempting to preserve a sense of social responsibility by retaining some administrative supervision and guilds on a voluntary basis. From 1821 to 1834 Hoffmann was also active as a professor of practical philosophy and cameralistics at the University of Berlin, a chair to which he was appointed in 1810. With his gradual retirement from active service after 1834 he devoted more time to writing. His books, resembling expanded official memoranda, reveal a great fund of common sense and practical experience rather than theoretical acumen.

T. von, in *Allgemeine deutsche Biographie*, vol. xii (Leipzig 1880) p. 598-604; Böckh, Richard, *Die geschichtliche Entwicklung der amtlichen Statistik des preussischen Staates* (Berlin 1863) p. 28-63; Roscher, W., *Geschichte der Nationalökonomik in Deutschland* (Munich 1874) p. 732-43.

HOFMEYR, JAN HENDRIK (1845-1909), South African journalist. In 1862 at the age of seventeen Hofmeyr was appointed editor of the *Volksvriend*; he soon became the most influential Dutch journalist in Cape Colony and an important force in the colony's politics. He entered the house of assembly in 1879, but it was chiefly through the press that he made his influence felt. He was governed by two main ideas: to foster a sense of South African nationalism based upon a fusion of the British and Dutch elements, involving recognition by each race of the rights and aspirations of the other; and to unite the various colonies in South Africa in some form of confederation. Hofmeyr became the champion of bilingualism as necessary in fusion based on equal rights and it is largely due to him that South Africa has now two official languages, English and Afrikaans. Other nationalists among the Dutch sought to reach their goal by repudiating the British connection, and to further this object the Afrikaner Bond was instituted in 1879. Hofmeyr, convinced that the realization of South African nationalism was impossible without British cooperation, turned the Bond from its anti-British bias and collaborated with Cecil Rhodes from 1890 to 1896 in the pursuit of South African confederation. The Jameson raid ruptured the alliance with Rhodes and led to the second South African War, lasting from 1899 to 1902. Hofmeyr remained loyal to his ideas and after the signing of peace encouraged the negotiations that resulted in the Union of South Africa. Although he personally favored confederation, the establishment of the union is the chief vindication of his life's work.

HOHENLOHE-SCHILLINGSFÜRST, CHLODWIG KARL VIKTOR, PRINCE OF (1819-1901), German diplomat and statesman. As premier of Bavaria from 1866 to 1870, he carried out nationalist and liberal policies. He

opposed the Catholic church and particularism and from his position in Munich endeavored to aid Bismarck's plans for the unification of Germany under Prussian leadership. After the foundation of the German Empire in 1871 Hohenlohe entered the service of the Reich. Bismarck sent him to Paris as the German ambassador and later appointed him governor of Alsace-Lorraine. For a time Hohenlohe was also a member of the German Reichstag, in which as a deputy he continued his support of Prince Bismarck's policies. In 1894 Hohenlohe, so advanced in years that he was no longer capable of energetic initiative, was appointed successor to Caprivi, whose chancellorship from 1890 to 1894 marked a violent departure from the policies of Bismarck. In foreign policy Caprivi had broken away from Russia, while in the realm of domestic politics his commercial treaties had brought him into sharp conflict with the landowning aristocracy of old Prussia. Hohenlohe's appointment was apparently to represent a return to Bismarck's methods. But in reality Chancellor Hohenlohe did not follow the Bismarck tradition in basic questions any more than his own tradition as Bavarian premier. During his chancellorship the government succeeded in forming an effectual Reichstag majority, consisting of the aristocratic Conservatives, the Catholic Center and the industrialist National Liberals. Henceforth until the end of the German Empire the party which held the balance of power in the Reichstag was with but few interruptions the Center. Hohenlohe left the actual conduct of foreign affairs to the secretary of state for foreign affairs, a post first held by von Marschall and later by Bernhard von Bülow. It was during these years that Germany rejected the British offer of alliance, while the great increase in the strength of the German fleet under von Tirpitz also contributed to the strain in Anglo-German relations. On the other hand, efforts for reconciliation with France and Russia failed. When Hohenlohe resigned in 1900 he left the German Empire in a grave diplomatic position.

HOHFELD, WESLEY NEWCOMB (1879-1918), American legal theorist. Hohfeld was professor of law at Stanford and at Yale. He is known

chiefly for his analysis of jural relations. As with Holmes, the starting point of his theoretical advance was his dissatisfaction with the current conception of "rights." He saw that the terms used in legal reasoning—contract, trust, property, easement—were persistently ambiguous and too broad for accurate use. His aim was, through an analysis of the concept of rights, to break these terms down into common elements that were manageable and capable of rigid definition. The result was a set of eight subconcepts which, to simplify their understanding and use, he arranged in a table of "opposites" and "correlatives." He narrowed "right" to a single meaning, a legally recognized demand of A against B; viewed from B's angle, this right is a "duty" to A. Such a right in A is sharply marked off from A's legal liberty to do something (e.g. use his own goods) without legally recognized objection by B; this Hohfeld called "privilege" in A; from the angle of the possible objector, B, it is a "no-right." Viewed dynamically, moreover, legal relations are subject to change. When A can by his action change B's legal relations he has a legal "power" to do so; B is then under a "liability." Absence of such power is "disability" in A, and "immunity" in B as against A.

While other writers had previously observed that rights might be analyzed into constituent varieties and Terry (*Some Leading Principles of Anglo-American Law*, Philadelphia 1884, p. 84-138) had even isolated and paired six of Hohfeld's subconcepts, it remained for Hohfeld to turn into an everyday working tool what had been a plaything of jurisprudence. He showed at times a tendency to accept these relations almost as entities in themselves. Thus he distinguished primary rights (as obtaining before a wrong was committed) from secondary rights (the legal consequences of the breach of primary duty). Insisting that rights and the other relations could obtain only between people, he accordingly reanalyzed "rights in rem" as clusters of rights in, say, an owner against every other person. He distinguished from legally irrelevant facts those "operative facts" which created or changed a legal relation and those "evidential facts" from which the existence of an operative fact could be inferred; here at times the operative facts also became to him rather entities than categories. Finally, carrying out the notion that the legal system "must be" a unit, he used his analysis to demonstrate a conflict between law and equity and to argue the supremacy of the latter. But in the ripper thinking of his last years

and especially in dealing with conflict of laws Hohfeld had begun to see his "relations" not as entities but as convenient summations of strong probabilities as to what courts would do if properly approached. Corbin and Cook, in developing Hohfeld's ideas, moved flatly into this position.

With some variation in terms Hohfeld's analysis has found acceptance. His own aversion to writing kept much of his systematization of positive doctrine, as in wills and evidence, from leaving permanent record. But the application and influence of his analysis are to be found in such writers as Corbin, Cook (especially in articles on the conflict of laws), Commons and Clark; and his analysis has been taken over in the pending restatement of the law by the American Law Institute. Such relevant criticism as Radin's that the correlative is misused or as Kocourek's that the privilege concept is not legal but extralegal leaves the pragmatic value of the analysis untouched. While it can obviously solve no cases it makes for clarification and cuts very close to the atomic structure of the law on its conceptual side. It was a happy accident that the same thinkers who from 1914 to 1925 were influenced by Hohfeld were being influenced also by Holmes' realism and by the pragmatic synthesizing approach of modern science. Hohfeld's new and powerful advance in analysis was thus kept from the sterility and the concept-contented inertia which has so often been the heritage left by a great analyst whose thinking along other lines was underdeveloped.

HOLBACH, BARON VON, PAUL HEINRICH DIETRICH (1723-89), French social and political philosopher. Holbach although of German descent spent his entire life in Paris. He was one of the most active of the group of *encyclopédistes*, and his salon became their principal place of meeting. The articles which he contributed to the *Encyclopédie* dealt with physics, chemistry, natural history, mineralogy and metallurgy, subjects which he had helped to popularize in

France by translations of scientific works from the German. It was only after 1756 that he began to publish anonymously or under various pseudonyms the works on natural, moral and political philosophy which taken together constitute the most typical expression in eighteenth century France of sensualist materialism and of social utilitarianism. Holbach's dynamic theory of matter and of life, as derived from Leibniz and more directly from Diderot and as presented in *Le système de la nature*, marks a departure from the time honored doctrines of Cartesianism. Uncompromising in his antipathy to religion in any form, whether traditional Christianity or the natural religion of Voltaire, he sought to eliminate the necessity of recourse to supernatural explanations or final causes by formulating the doctrine that, while matter is eternal, all bodies and all beings possess a capacity for independent movement according to their particular genius. Universal necessity, an adequate explanation of the natural order, governs equally the moral order and the relations between human beings, who are motivated by nothing more than the selfish quest of pleasure and the avoidance of pain, even when they are forced as a result of their inequalities and mutual dependence to seek incidentally the welfare of their neighbors. Where the individual is not sufficiently enlightened to realize the dependence of his personal welfare on the common welfare, it is the duty of society to emphasize these broader relationships by a system of sanctions freed from religious perversion. Antipathy to religion was the starting point of most of Holbach's ideology. Like the Epicureans he inveighs against the fears and fantastic hopes raised by religion, which lead men to excesses of intolerance and persecution. The invention of calculating obscurantists, religion distorts philosophy, confounds morality and by fostering an unnatural otherworldliness is the enemy of society. With the elimination of religious superstition the way would be open to intelligent political legislation directed solely toward a system of secular education which should concentrate on promoting sentiments of good will and universal philanthropy, such as the Freemasons of the time were championing. In general Holbach's political ideas are much less precise and incisive than his strictures on religion. He advances a system of natural politics based upon the needs common to all men but at the same time attempts to combine with this the theory, borrowed from the French jurists, of basic laws

of the kingdom resting upon a past contract between sovereign and people.

HOLBERG, BARON LUDVIG, (1684-1754), Norwegian-Danish satirist, historian and moral philosopher. Holberg was born in Bergen, studied at the University of Copenhagen, traveled widely throughout Europe and was professor of metaphysics and later of history at the University of Copenhagen. He was the most important representative of the Enlightenment in Scandinavia and at the same time the creator of the national literature of both Norway and Denmark. His sojourn in England from 1706 to 1708 had greatly influenced the forming of his mind but he acknowledged Bayle and Molière as his chief teachers. He thus represents the combination of English thinking and French *esprit*.

The works of Holberg cover a wide variety of subjects. There is hardly any problem of his time, moral or religious, economic or political, literary or historical, that is not discussed in his works. In his comedies, which he wrote chiefly between the years 1718 and 1725, in his utopian novel *Nicolai Klimii iter subterraneum* (Copenhagen 1741, ed. by C. G. Elberling, 1866; tr. by John Gierlow, Boston 1845), in his ecclesiastical history, his volume of moral thoughts and his five volumes of epistles he sought to show in concrete examples the varieties of human nature, to fight against all sorts of obscurantism and prejudice and to teach his readers to discern real and apparent virtue and vice. He hated theorizing as well as fanaticism and liked to con-

sider every question from two sides, testing how far it was possible to go in both directions and then at last returning from the extremes to the *medium magnum*.

As a historian Holberg is most famous for his *Dannemarks og Norges beskrivelse* (Copenhagen 1729) and *Dannemarks riges historie* (3 vols., Copenhagen 1732-35), which laid the foundations for the writing of Danish and Norwegian national history. The first of these gives an excellent description of the national characters of the Danes and the Norwegians and of the economy, institutions and later history of the two united kingdoms. The second is an attempt at a complete history of Denmark; it is not written in the old annalistic style but well composed, vivid and based on selected source material. His earlier historical works were introductions to modern European history and to the law of nature and international law. He followed Pufendorf more or less closely in these but his defense of royal absolutism was written as a patriotic apology for the Danish-Norwegian monarchy and against the argument of Molesworth, the English Whig of 1689 who in his bitter *Account of Denmark* (London 1694) had tried to show the fatal results of absolutism.

Quotations from Holberg's works have often been used to support many different theories and tendencies in Norwegian and Danish life. Any attempt to rubricate his principles, however, is bound to fall short, for his thinking was too many sided to be consistent.

FRANCIS BULL

Works: Of the first complete edition, *Samlede skrifter*, ed. by C. S. Petersen and calculated to contain 20 volumes, only vols. i-x, and parts i-iii of vol. xix (Copenhagen 1913-30) have appeared so far.

(Copenhagen 1920-25); Holm, E., *Holbergs statsretlige og politiske synsmaade* (Copenhagen 1879); Høst, S., *Om Holbergs historiske skrifter* (Bergen 1913); Bull, F., *Ludvig Holberg som historiker* (Christiania 1913); Prutz, R. E., *Ludvig Holberg* (Stuttgart 1857); Brandes, G. M. C., *Ludwig Holberg* (2nd ed. Copenhagen 1898), German translation (Berlin 1885); Campbell, O. J., *The Comedies of Holberg*, Harvard Studies in Comparative Literature, vol. iii (Cambridge, Mass. 1914).

HOLBROOK, JOSIAH (1788-1854), American educator. Holbrook, a Yale graduate, was a gifted teacher, especially of the natural sciences, and was probably the first in the United States to combine manual labor with book education.

His geometry textbook and his standard collection of articles for school use in illustrating geometry and astronomy and in performing simple experiments were very popular. His chief work was in popularizing science, improving schools and forwarding adult education by mutual instruction. All these were embraced in the program of the lyceums, the first of which he organized in Millbury, Massachusetts, in 1826. The idea was received with enthusiasm, and by 1834 there were in the United States nearly 3000 town lyceums as well as scores of county lyceums and at least eight state lyceums, the latter two forms being unions of town lyceums. These were in some ways like the present day parent-teachers' associations and served to quicken popular interest in school problems. Holbrook was one of the first to suggest normal schools for teachers and took the lead in the Lyceum Convention which in 1830 organized the American Institute of Instruction, forerunner of the National Education Association. The lyceums gave a great impulse to general cultural activities, and, although few remain as they were in Holbrook's day, the institutions of the next generation—debating societies, young men's institutes and library associations with their lectures and classes—as well as the lecture foundations and the scientific lectures of today developed directly from Holbrook's work.

HOLDHEIM, SAMUEL (1806-60), Jewish reform leader. Holdheim was one of the most prominent pioneers of the Jewish reform movement in Germany. Holdheim's reform ideas were definitely conditioned by the struggle for Jewish political emancipation, which met with opposition because of the fact that the Jews had in several states retained some features of political autonomy. Holdheim emphasized the divine and moral teachings of Judaism and its character as a universal religion and accepted the distinction drawn by Napoleon between the eternally true and generally valid religious elements of Judaism and the temporary and only conditionally valid national elements. He also preached the necessity of returning from rabbinic Judaism to Mosaic; he declared, however, that the political elements in the Mosaic religion were long since obsolete and that the extension of their influence

after the fall of the theocratic state had been due only to the Talmudic-rabbinical interpretation of the Bible. He retained, however, the religious idea of the sanctity of the state as a divine institution and of the law of the land as divinely sanctioned.

Holdheim's theology although it received considerable attention in his own time exercised no deep influence on posterity. His theories were based too much on current affairs and too little on the more fundamental principles of religion. Moreover they were proved by means of an extremely acute dialectic, retained from his Talmudic studies, which could not withstand scientific criticism. His arbitrary distinction between the religious and the national cannot be reconciled with his profession of a "pure Biblical, positive belief in revealed religion"; and his rejection of the particularist doctrines of Judaism was accompanied by a recognition of the particularism of the political states. Finally, in his overestimation of the state, probably inspired by Hegel, he does not consider the possibility of the adoption by the state of policies to which obedience can in no way be urged as religious law; as, for example, in the case of definite antireligious legislation.

In regard to religious practise Holdheim adhered to the radical wing of the reformers and became the first rabbi of the Jewish Reformed Congregation in Berlin. Many of the traditional practises of Judaism, such as the Sabbath, circumcision and the dietary and marriage laws, were discarded. Although completely isolated in Europe this congregation exercised considerable influence on the institutions and practises of American Reform Judaism.

HOLDING COMPANIES

UNITED STATES. A holding company may be defined in the broadest sense as any company having share capital which owns securities of one or more other companies. In a more restricted but more usual sense the definition is made to turn not on ownership in but on control over another company. A holding company may thus be defined in terms of its distinguishing charac-

teristic as any company with share capital which is in a position to control or materially to influence the management of one or more other companies by virtue, in part at least, of its ownership of securities of the latter. A holding company may be classed as a pure holding company if its assets are composed almost entirely of the securities of other companies, and as a parent holding company (or parent company) if in addition to the ownership of such securities it conducts an operating enterprise as a directly owned property. In the United States the holding company is usually a corporation, occasionally a Massachusetts trust.

The holding company is recognized as a characteristically American form of combination. It began its career as an important institution of business enterprise in the last decade of the nineteenth century, although it was not unknown before that time. Before 1888 few corporations had the legal power to own stocks of other companies. Such power was regarded as dangerous and unsuitable for a corporation, much as today a partnership between corporations or the incorporation of law firms is regarded as improper. The courts of most states (Maryland and California *contra*) accepted the principle that at common law a corporation has no power to own stock in another corporation and that such power can be derived only from specific legislative enactment. The general corporation statutes of certain states, notably New York (1811), Illinois (1849), Maryland (1860) and Pennsylvania (1874), expressly excluded the power to hold stock from the powers that might be granted corporations under the law. Before 1888 no state expressly granted in its general laws the power of intercorporate stockholding. Such holding companies as existed usually derived their power to hold stock from special legislative acts. Thus in 1832 the Baltimore and Ohio Railroad Company was empowered by the Maryland legislature to acquire the stock of certain connecting railroads. In 1853 the Pennsylvania Railroad Company was granted power by the Pennsylvania legislature to own stocks of other railroads up to 15 percent of its capital. The Western Union Telegraph Company acquired power to own stocks of other telegraph companies before 1864. Sixteen years later the American Bell Telephone Company was created by special act of the Massachusetts legislature and empowered to own stocks of other telephone companies.

In contrast to companies whose right to own stock was limited to the stock of certain other

companies or to companies in a particular industry, a few early corporations were created by special acts which granted them extremely broad powers including the power to hold the stocks of any other companies. Most notable of these were a group of over forty corporations created through charters granted by special acts of the Pennsylvania legislature between 1868 and 1872. One of these, the Pennsylvania Company, is still employed as a major element in the Pennsylvania Railroad system and is perhaps the first example of a pure holding company. Another of these broad charters, that of the ill fated South Improvement Company, was the vehicle through which the Standard Oil interests created their notorious system of rebates. The broad charters now held by the Reading Company (Reading railroad), the Philadelphia Company (electric power) and the United Gas Improvement Company were products of this burst of legislative generosity. Because of the furor created by these charters the Pennsylvania legislature passed an act in 1874 forbidding the creation of additional corporations with such broad powers.

In 1888 the state of New Jersey first made possible the extensive use of the holding company by amending its general stock corporation law so as to enable all companies formed under it to include in their charter the specific power to hold stocks in other corporations. This provision was clarified and extended in the following year and still further broadened in 1893. Other states were forced by competition for charter business to adopt similar provisions. Between 1892 and 1899 the lead of New Jersey was followed by New York, Connecticut, Pennsylvania and Delaware. By 1929 thirty-nine states had expressly authorized intercorporate stockholding. Thus in a period of forty years the holding company, which had been regarded as undesirable and contrary to public policy except under unusual conditions, was made by most states an acceptable and legal practise.

Once the holding company became available as an instrument for the conduct of enterprise, its uses began to multiply. Most important of all is its use as the most effective device yet invented for combining under a single control and management the properties of two or more hitherto independent corporations. The combination of two independent companies by complete fusion requires a majority (usually two thirds) or unanimous agreement of the stockholders and may involve difficulties with the contractual rights of bondholders as well as the risk of lawsuits by

dissenting stockholders. The acquisition of stock control of one corporation by another is relatively simpler and less costly than direct fusion; it can be accomplished gradually and without publicity, requires no action by the stockholders of the company being acquired and in no way affects the position of existing bondholders. Furthermore the ownership of any remaining stock of a controlled company can be acquired gradually, over a period of years, as occasion makes desirable. By thus facilitating combination the holding company has made possible the development of giant systems of business enterprise at a pace far more rapid than would have been feasible by any other method. Only by the use of the holding company or some similar legal device would it have been possible to create the multibillion dollar enterprises typified by the American Telephone and Telegraph Company, the Insull system of electric light and power properties, the United States Steel Corporation and the Pennsylvania Railroad system. Without the power to purchase controlling stock interests in other companies the concentration of capital into larger units would certainly have been of slower growth than is shown by the figures of the last decades.

Of scarcely less significance is the use of the holding company by business men as a means of avoiding social control. The term social control is used here to mean all forms of regulation and publicity designed to protect the interests of the investing, working and consuming public against exploitation by the persons who dominate a business enterprise. It includes not only governmental regulation but also the informal although often more effective control imposed by rules of the stock exchanges and by pressure of investment bankers, banks and private investors. Partly because the holding company is a comparatively new device, partly because it is protected from interference by traditional American interpretation of constitutional law and partly because it often extends beyond the jurisdiction of any one state it has so far been to a considerable extent, although not completely, exempt from the restrictions to which other business corporations have been subject. Employed to evade the restrictions of the Sherman Act at the close of the last century, the holding company has been made as subject to dissolution as any other form of restraint of trade. In the public utility field it has been much more successful in avoiding regulation through its ability to escape control of service charges, financial practises and

accounting publicity to which the operating utilities have been subjected. Moreover, in spite of the publicity of accounts in a measure imposed by the investment world on large companies with a widely distributed stock ownership, the holding company has often been most successful in concealing its operations.

Bound up with the avoidance of social control has been the use of the holding company to facilitate capital inflation, a use generally associated with other purposes. Bonds and preferred stock as well as common stock of the top company can be issued against junior securities of subsidiaries held in its treasury, so that the total securities issued and in the hands of the public can often be made very much greater than could be issued directly against the underlying property.

The use of the holding company involves another serious drawback in that it may create or further weaken the position of a minority interest. At best the position of minority stockholders is weak. If the majority stock is owned by a holding company, the stockholders' position is further weakened by concentration of control in a single block which acts as a unit and by the opportunity which the holding company has of trading with the controlled corporation (directly or through subsidiaries) to the disadvantage of minority interests. Transactions between a holding company and its subsidiary or between two subsidiaries of a single holding company do not involve independent parties. The holding company is in the position of dealing with itself, and there is grave danger that the interests of the minority will not be protected. Only as the holding company acquires all the outstanding securities of its subsidiaries does the problem of minorities disappear.

An important use of the holding company is to maintain legal control of an underlying corporation with a minimum of investment. This is accomplished by a pyramided series of holding companies. Control of the base operating company is held by a holding company through the ownership of a bare majority of the voting stock. This holding company in turn is controlled by another in a similar manner, with the result that the third company is in a position to control the first with only a quarter interest in the stock of the latter. The pyramiding may go even further, each additional company reducing the investment necessary for the control of the underlying company. Where each company in the series has bonds and non-voting preferred stock outstand-

ing, the reduction in the investment necessary for control diminishes even more rapidly, so that a pyramid involving three holding companies will allow, say, a one-million dollar investment in a top holding company to control a billion-dollar operating company. The investment necessary for control may be made even smaller by issuing non-voting common stock or stock with limited voting power.

Another important use of the holding company is as a permanent aid in decentralizing the administration of great modern combinations. By maintaining separate branches of an enterprise as separate corporations with separate and semi-independent boards of directors the management of a concern can conduct it more as a group of federated enterprises than as a single armylike organization. Some of the advantages of combination can thus be obtained without the surrender of all the advantages of smaller organizations. In larger matters the activity of the separate units can be brought into harmony at the same time that in more local and immediate matters each unit can be operated as an independent enterprise. Although decentralization could undoubtedly be accomplished by other means, the holding company is perhaps the most effective instrument for bringing it about.

The degree of decentralization varies with different holding companies. At one extreme, the operations of the constituent companies may be unified, perhaps even to the extent of obliterating corporate lines. On the other hand, financial control alone may be centralized, with the credit of the holding company or even the credit of the underlying companies as the basis of new financing, while the operations of subsidiaries are conducted as if they were independent. Between these extremes the great flexibility of the holding company allows any degree of decentralization desired. The extent to which the holding company is being used as an aid to decentralization of administration is difficult to ascertain; but that it is so used extensively is suggested by the persistence of the holding company long after complete fusion has become easily possible.

Other uses of the holding company deserve mention, such as the separate incorporation of properties in different localities in order to simplify the adjustment of corporate activities to the laws of particular countries and states. Property in a particular state is often separately incorporated to simplify the problems of accounting and taxation, to avoid taxation or to take advantage of special laws of that state. The hold-

ing company thus intensifies the problems growing out of the taxation of an enterprise which owns property in two or more states and the allocation of its property to particular states. It is also customary for American industrial corporations to conduct their operations in foreign countries through subsidiaries incorporated in the respective foreign countries. The Standard Oil Company, the United States Steel Corporation, General Motors and other large corporations control a series of such subsidiaries. In addition holding companies are sometimes formed to secure control of enterprises in foreign countries, as in the electrical manufacturing and communications industries. International holding companies are also formed by competing interests to apportion markets and reconcile conflicting interests.

Sometimes separate branches of a business involving different risk factors are separately incorporated, in a measure to insulate the less risky part of a business from the effects of loss by the more speculative branch.

Frequently personal holding companies are formed to hold the securities of an individual or family. By this means the making of tax returns can be simplified, taxes can often be reduced and family holdings can be maintained and voted as a unit, even though through inheritance the ownership interest becomes subdivided in successive generations.

It has frequently been stated that the holding company was largely developed after 1890 as a substitute for the trust form of combination, which had been outlawed by the courts as a device for maintaining monopolistic combination. This was a slow process, however, and quite as often the use of the holding company can be explained on the ground of its convenience relative to fusion rather than that of its possible freedom from dissolution. During the 1890's the holding company was a comparatively untried device and few lawyers were sufficiently bold to recommend it to their clients. Outright fusion was regarded as safer. Before 1898 out of the ten major monopoly seeking combinations formed after the passage of the New Jersey law which made possible the extensive use of the holding company only one, the American Cotton Oil Company, took this form. The remainder involved outright fusion of properties. Even in the hectic merger years of 1898 and 1899, when so many horizontal combinations were formed, the holding company was used less frequently than fusion. Of forty-one important combinations ac-

complished during those two years only six made use of the holding company. The most important of these was the reorganized Standard Oil Company. In 1899 the Standard Oil interests, whose informal combination was being threatened by antitrust proceedings, amended the charter of the Standard Oil Company of New Jersey and obtained for that company the power to hold stocks. Thereupon it acquired the stocks of the other Standard units and became primarily a great parent company.

This use of the holding company by the powerful Standard Oil interests gave impetus to its further employment. In the four years from 1900 to 1903 the holding company vied with fusion as the most important form of combination. Among the more important holding companies formed during this period were the United States Steel Corporation, the American Locomotive Company and the Eastman Kodak Company in 1901, the International Nickel Company in 1902 and the Du Pont de Nemours Powder Company in 1903. Whether the holding company was used during this period simply because of the ease with which combination could be effected or whether its use was due to a belief that it might be in less danger from antitrust proceedings than the fusion, it is difficult to say. No federal antitrust suits had been instituted against fusions after the unsuccessful Knight case in 1894 and prior to the latter part of 1902. There was therefore little to indicate that outright fusion was not quite as safe as the untried holding company for bringing about a monopoly seeking combination. Presumably its great flexibility determined the use of the holding company in spite of the risk involved in its uncertain legal status.

Any belief that the separate corporate entity of the holding company might make it immune from attack under the Sherman Act was dispelled by the decision of the Supreme Court in the Northern Securities case in 1904 which put an end to the use of the holding company as a legal means for maintaining monopoly. In the following ten years few industrial holding companies were formed, the General Motors Company (1908) being the largest. In 1911 the Standard Oil Company was dismembered as a result of antitrust proceedings, and a still further disability was placed on the holding company as a tool of monopoly by the passage of the Clayton Act in 1914, which made it illegal for a corporation to acquire stock in another corporation engaged in interstate commerce where the effect

might result in a substantial lessening of competition between these two companies. Although the courts have interpreted competition in a somewhat limited sense, this clause combined with the antitrust decisions of the courts has forced combinations involving competing units which operate across state lines to take the form of fusion. There can be little doubt that its effect has been to retard although not to prevent industrial combination.

In recent years the holding company appears to have been used almost invariably in combining large companies, except where the danger of proceedings under the Clayton Act has been considered serious. Of the ninety-seven largest industrial companies in the United States at the beginning of 1929 (measured by assets) twenty-one were pure holding companies, thirteen were parent companies with a third or more of their controlled assets in subsidiary companies, and sixty-three were operating companies although most of them had one or more small subsidiaries. It is noteworthy that of the large companies formed before 1920 sixty-two were operating and only eight were pure holding companies. Of those formed since 1920 only one was operating and thirteen were pure holding companies.

Since the passage of the Clayton Act in 1914 the most important single use of the industrial holding company has been in the consolidation of enterprises which were largely non-competing; that is, in the creation of circular or of vertical combinations. The typical consolidation by means of the holding company has involved either the acquisition of stock control of a smaller concern by a large established company or the creation of a new holding company which acquired stock control of two formerly independent and complementary companies. In either case the initial stock control may have involved less than a majority of the voting stock, although usually it has represented at least a majority. In most cases additions have been made to the initial stock interest, until after a period of a few years the ownership of all or nearly all the outstanding stock of the subsidiary has been obtained. Only infrequently has a pyramided capital structure been built up in order permanently to maintain control with a minimum of ownership. The tendency is for subsidiaries to be wholly owned.

While the holding company has been a very important factor in industrial integration it has played its most conspicuous role in the public utility field. The Bell Telephone Company,

which was chartered in 1880, has already been referred to as probably the first pure holding company in this field. The present United Gas Improvement Company, organized in 1888 as a holding company, is regarded as the first of the gas and electric holding companies. Early in the development of the electric light industry the two great equipment companies, the Westinghouse Company and the General Electric Company (or its predecessors), initiated the practise of aiding the purchasers of their equipment by accepting their securities in payment. Westinghouse thus became a parent company, while the General Electric deposited the securities received with a series of holding companies which ultimately developed into the present Electric Bond and Share Company system. Within the last two decades the extension of the holding company device has been extremely rapid, until today ten great groups of holding companies control three quarters of the electric light and power business and 40 percent of the gas business of the country.

In the utility field the holding company has been employed primarily as an aid in the up-building of great systems, as a method of maintaining control of these systems with a small investment and as a means of avoiding control by state regulatory commissions.

By the acquisition of stock control of one company after another utility properties distributed in different parts of the country have been brought within a single system, often with little regard to the possibilities of unified operation. Frequently the desire to control a large number of properties has arisen from the desire to sell services to controlled companies. This was the case in the creation of the Bell Telephone Company and the United Gas Improvement Company, the one to further the development of its telephone patents, the other to develop its patented water-gas process. More frequently the services rendered to controlled companies have been engineering, managerial and financial. Whatever the service supplied, the larger the aggregate of properties controlled, the larger the profits to be made. Under such conditions the main advantage to the promoters lay in increasing the properties controlled as rapidly as possible and with the minimum investment. The holding company served both purposes, and today the typical utility system is composed of a series of holding companies and a multitude of operating companies. In recent years a process of simplification has been going on: contiguous

operating companies have been fused, intermediate holding companies eradicated and financial structures simplified. There remains, however, the increasing use of the holding company pyramided structure, whereby control is maintained with a small investment. The investment necessary for control is frequently made even smaller by the issuance to the public of non-voting stock or of stock with limited voting power, while the promoters retain control through ownership of the comparatively small amount of voting stock.

The use of the holding company to avoid public utility regulation involves a problem which has become more acute in recent years, particularly as an increasing amount of electric power or gas is transported across state lines. The holding company has avoided state regulation on the ground that it is not a public utility. Though the local operating companies are subject to commission regulation, the transaction between the operating company and the holding company or one of its affiliates is not subject to full control, since a commission cannot examine the books of the latter to determine the fairness of such transactions. As these are clearly between interested parties, the presumption of fairness which is applicable to dealings between independent parties does not exist. The difficulty is further aggravated by the character of the transactions, which are as a rule difficult to evaluate, particularly the charges for engineering, management and financial services. An additional difficulty arises with respect to the issuance of securities by the holding companies. In many states the security issues of operating companies are closely supervised. Those of holding companies, with which the credit of the operating company is linked, are unsupervised, a fact which has frequently led to inflation with its repercussions on rates and on quality of service.

In addition the utility holding company is extensively used to decentralize administration. The outstanding example is the American Telephone and Telegraph Company; most of its subsidiaries are managed by independent boards of directors, mainly local business men and executives in the district in which the subsidiary operates. The general policy of the system can be maintained at the same time that a large degree of autonomy is given to the local units. This type of decentralization exists also in some of the other large utility systems. Particularly is this true of the United Corporation, formed in 1929, which has working control of or substantial influence over a number of gas and electric

holding companies whose combined assets approach those of the American Telephone and Telegraph Company.

In the railroad field the holding company has played an important role from the very beginning of the industry. For the most part it has taken the form of the parent company. In the gradual upbuilding of the existing great systems a large operating company would acquire stock control of connecting lines, gradually absorbing their property into its own system or operating them as separate units. Since the operating companies in the position of parent are subject to Interstate Commerce Commission jurisdiction, the acquisitions are largely regulated.

There are, however, certain notorious examples of the use of the pure holding company. Among them were the now defunct Rock Island Company, involving an extremely inflated pyramid of companies, and the Northern Securities Company. In recent years two new and important pure holding companies have been formed in the railroad field. With the passage of the Transportation Act in 1920 the approval of the Interstate Commerce Commission was made necessary in carrying out any consolidation. To avoid the necessity and difficulty of obtaining such approval in the creation of a great fourth eastern railroad system the Van Sweringen brothers made use of a series of holding companies culminating in the Allegheny Corporation formed in 1929. By this corporate pyramid they were able to bring a number of operating railroads under common control without the approval and contrary to the published plans of the commission and thereby to create the largest system of railroads in the country. In 1929 the Pennroad Corporation was also formed as a pure holding company by the Pennsylvania Railroad management; it was employed as a vehicle for obtaining stock control of or stock interests in other roads, also without approval of the commission. Although the Pennsylvania Railroad Company has no stock interest in the Pennroad Corporation in effect it controls the latter through a voting trust and through interlocking directors, so that the Pennroad Corporation may be regarded as a tool of the railroad company. These holding companies have not been subject to control of the Interstate Commerce Commission. However, the ownership of all railroad stocks by other railroads and by holding companies has been the subject of a recent congressional investigation which may lead to a measure of regulation.

Where the pure holding company has been employed in the railroad field it has frequently been used to avoid regulation in one form or another. In part it has been used to maintain control with a small investment. Only to a small extent has it been used to accomplish legitimate combination. In contrast to this, the parent company has consistently been employed in the long process of consolidation.

Recently the holding company has been extensively employed to avoid the social control of banking. Here it has been used to defeat the purpose of state and federal banking laws restricting branch banking. Contrary to the practise and policy of most foreign countries the banking system of the United States has been developed on the basis of the independent local unit bank. Federal law with respect to the national banks and state laws with respect to the state banks (in the bulk of the states) prohibit branch banking. By the use of the holding company it has been possible to bring a large number of banks under the control of a single organization much as if they were all branches of a single bank. In 1926 only a few insignificant banks were controlled by holding companies. By the end of 1929 thirty-eight holding companies controlled over five hundred banks with combined resources of over \$8,000,000,000. With one exception these banks were in states not allowing branch banking. Under the circumstances it is doubtful if the holding company would have been employed so extensively to combine independent banks had branch banking not been prohibited.

The holding company is a relatively new instrument of industrial organization subject to abuses but also to many desirable uses. It can be employed as a device for avoiding social control. On the other hand, if concentration of industry is a desirable end, the holding company can be an invaluable aid in bringing it about. Once combination has been accomplished, the holding company is useful for maintaining decentralized operation and authority while ultimate control is centralized. The holding company may be well or ill used. The advantages which it offers deserve recognition, while the abuses to which it is subject must be progressively curbed.

JAMES C. BONBRIGHT
GARDINER C. MEANS

EUROPE. Holding companies organized for the special purpose of acquiring control of other companies must be distinguished from holding companies of the investment and financing type;

the latter are more important in Europe than the holding company used for combination purposes. While this article is primarily concerned with the pure holding company of the monopolistic type, it must not be overlooked that there are also frequent cases of operating companies which have become holding companies by incorporating their plants into separate companies and retaining the possession of their share capital. Typical examples of this are the two parent companies of the Siemens-Schuckert concern—the Siemens und Halske A.-G. and the Elektrizitäts A.-G., formerly Schuckert & Company, the latter now a pure holding company. Another form of development into the holding company appears in the parent companies of the Vereinigte Stahlwerke A.-G.—the Gelsenkirchener Bergwerksgesellschaft, the Deutsch-Luxemburgische Bergwerksgesellschaft, the Phönix A.-G. für Bergbau und Hüttenbetrieb and the Charlottenhütte A.-G.—which transferred all or nearly all of their plants to the Vereinigte Stahlwerke and turned into holding companies owning the majority of capital stock of what is now the largest coal, iron and steel enterprise in Europe.

While isolated instances of holding companies in Europe date back to the sixties, their real development did not occur until the eighties of the last century. In 1886 the Nobel Dynamite Trust Company, Ltd., the first European trust, was formed in London. It comprised at first two (later three) English companies, four (later six) German companies and one company each in Switzerland, Mexico and Brazil. The Nobel Trust entered into agreements with the Société Centrale de la Dynamite in Paris, which was itself a holding company organized in 1887, and later with the German cartel of gunpowder factories, thus attaining a monopolistic position which spread beyond the borders of Europe.

During the following decades numerous holding companies were formed in all industrial European countries. But the holding company never assumed the same significance in Europe as it did in the United States. Reasons for this are the more limited use of the stock company as a form of business enterprise and the greater degree of legal regulation and government supervision over the formation of corporations, the issue of securities and all other phases of corporate activity. Also the railroads and public utilities, a favorite field for the operation of holding companies in the United States, were and still are government owned in most European coun-

tries; and even where privately owned, as in England and France, they were and still are removed from financial manipulation and stock market speculation to a greater extent than in the United States. Furthermore the object of monopolistic control, which was the moving spirit behind many a holding company in the United States, could at least in most European countries be reached through the organization of cartels. Seldom therefore was the holding company used for purposes of obtaining monopoly; the Nobel Trust Company, Ltd., and the Reis- und Handels-A.-G., a trust of German rice millers, remained isolated phenomena up to the World War. In England, where legislation interfered with the formation of monopolistic combines, most of the large combinations were effected through mergers. After the World War, however, several holding companies of monopolistic nature were formed in England; the most important of these is the Imperial Chemical Industries, Ltd., with authorized capital of £95,000,000, of which £76,200,000 is outstanding; it owns the stock of fifty subsidiary companies.

Where monopoly was the main object of combination the holding company found its widest application in the case of industries of wide international scope with plants and branches located in different countries. The separate incorporation of the foreign plants facilitated the adjustment of corporate activity to the varying legal requirements of the respective countries, while a special holding company retained the stock of all corporate units for purposes of control. Among such holding companies are the Continentale Linoleum Union in Zurich, a strongly monopolistic combination of German, Swiss, Swedish, Dutch and French linoleum producers; Lever Brothers, Anton Juergens Vereenigde Fabrieken, Van den Bergh's Fabrieken, an almost monopolistic combination of Dutch-English soap and margarine producers, known since 1930 as Unilever, Ltd. There are also numerous holding companies in the Dutch-German artificial silk combine, the Algemeene Kunstzijde Unie N. V., in the great English-Dutch petroleum combine, the Royal Dutch Company, and in many other international concerns.

The use of holding companies in domestic industries is rather limited. In Germany particularly but also in England and in other European countries the rationalization movement seemed to favor merger as the more compact form of business combination. Only the extreme multi-

plication of political boundaries which cut across economic regions prompted the organization of holding companies in enterprises which although predominantly national in scope nevertheless extend their operations beyond the narrow national frontiers. The most significant of such non-monopolistic holding companies are above all in the electrical industry—the Société Financière de Transports et d'Entreprises Industrielles (Sofina), the Bank für Elektrische Unternehmungen, the Gesellschaft für Elektrische Unternehmungen, Motor-Columbus A.-G. für Elektrische Unternehmungen (Brown-Boveri), the Schweizerische Gesellschaft für Elektrische Industrie (Siemens-Halske), Société Internationale d'Énergie Hydro-Électrique (Sidro) and others.

The holding company is of some significance in the utilization of patents. In order to exploit patents on an international scale special companies must be formed in various countries, the stock of which is for the most part transferred to the patent utilization companies which in this way become holding companies. Such companies favor having their domicile in countries of pronounced neutral character like Switzerland and Holland.

Many holding companies, particularly the international, are at the same time finance companies; that is, they supply a large part of the capital requirements of subsidiary enterprises. The disproportionate international distribution of wealth which was brought about during and after the World War furthered the use of holding companies, particularly in the international field, as a convenient form of control of foreign enterprises. The holding company thus quickened the pace of capitalistic interpenetration. The development of holding companies into finance companies is especially clear in the Swedish match combine (Kreuger and Toll A. B., International Match Corporation and others) which went into liquidation in 1932 following the suicide of its guiding spirit, Ivar Kreuger. Despite the ownership of about 250 match factories in forty-three countries it had more of a financial than an industrial character. It received in numerous countries a monopoly of the manufacture or sale of matches in return for loans to the government, which are in the final count responsible for its collapse.

The pure holding company is perfectly free in the choice of domicile and prefers the country in which legislation and taxation are most favorable. Some of the Swiss cantons and recently the

grand duchy of Luxemburg and the principality of Liechtenstein have the same significance for European holding companies that New Jersey and Delaware have in the United States. Switzerland was a particularly popular choice of domicile in the post-war era, partly because it provided neutral ground for resuming the threads of international combination which were torn during the World War, and partly because of its political and monetary stability, which was particularly attractive to investors from countries with a depreciating currency. Liechtenstein and Luxemburg especially facilitated the forming of holding companies by liberal legislation in 1928-29. In Liechtenstein the Standard Oil has formed the International Company of Vaduz, which combines all its European shipping interests. Liechtenstein is also the home of the International Hydrogenation Patents Company, the joint patent utilization company of the I. G. Farbenindustrie, the Standard Oil Company of New Jersey, the Royal Dutch Company and Imperial Chemical Industries, Ltd. The principality and some Swiss cantons permit such companies to make special agreements with the tax authorities with a view to eliminating multiple taxation. The generosity of these states toward holding companies makes it more difficult for the other states to regulate some of the abuses of which holding companies may be guilty and encourages the use of the holding company as a convenient vehicle for the flight of capital from burdensome regulation and taxation. This may have both a favorable and an unfavorable influence on the international distribution of wealth.

The dangers of the holding company are manifold; it may be used by financiers for speculative purposes or to unload securities which they no longer care to own, or it may be formed for the sole purpose of bringing business to the parent companies. Of more general significance is the fact that holding companies may increase the capital demands in the national economy and thereby increase the disproportion between capital accumulation and consumption—one of the chief causes of crises.

HOLIDAYS. In every civilization the round of daily work has been interrupted by periods of communal relaxation and repose. The holiday, a closet philosopher might assume, is very simply accounted for by considerations of practical utility: it is due to man's need of at least occasional relief from toil and the harsh conditions of existence. But its origins are not so simple. The holiday in most cases does not seem to have begun as a secular institution; its first and original form was the holy day, a time set apart for religious observances of a public and ceremonial character. "The gods," said Plato, "in pity for the toils which our race is born to undergo have appointed holy festivals, by which men alternate rest and labor" (*Laws*, II: 653).

The festal remission of labor on a holy day is the consequence and not the cause of its observance. The suspension of ordinary activities forms a measure of spiritual protection and propitiation quite as much as the sacrifices, prayers and other religious exercises on such an occasion. To primitive man the holiness which attaches to certain persons, objects and places is sufficiently material to be transmissible and to be capable of affecting with its qualities whatever is done at a particular epoch. In short, a period of time may be sacred, as well as a divine chief or king, an idol, an altar or a mountain. This notion of the transmissibility of holiness might seem of itself to provide a sufficient reason for not working on a holy day: the power that blesses can also blast. In practise, however, it mingles quite inextricably with the opposite although related conception that what is holy can be contaminated by contact with the secular and the profane. Furthermore, when holy days are consecrated to divinities or to semidivine

beings, who are then believed to be present among their worshipers, the notion easily arises that a god is pleased and flattered by the enforced idleness of his devotees. Abstinence from work takes its place among other rites as a recognized means of expressing reverence for the god; while, conversely, to labor on his holy day implies a disrespectful attitude toward him. "Sacred holidays, and holidays generally," writes Thorstein Veblen, "are of the nature of a tribute levied on the body of the people. The tribute is paid in vicarious leisure, and the honorific effect which emerges is imputed to the person or the fact for whose good repute the holiday has been instituted . . . *Un saint qu'on ne chôme pas* is indeed a saint fallen on evil days" (*The Theory of the Leisure Class*, new ed. New York 1918, p. 310).

Some holy days are feasts, such as those which in the lower cultures mark clan and tribal rites, the beginning or end of the hunting and fishing seasons, the inauguration or close of agricultural operations and certain times of calendrical importance, including new moon and full moon, the solstices and equinoxes and the rising or setting of various constellations, notably the Pleiades. Well defined anniversaries marking important events in the communal life give rise in a further development to festive holy days. There is a general tendency to convert the earlier seasonal observances into those of an anniversary character, as the Hebrews associated Passover, Tabernacles and Pentecost—all originally agricultural feasts—with episodes of their tribal history. Such feasts often form a part of the sacrificial rite: they are religious barbecues. The god is supposed to be satisfied with only a small part of the offering or with merely its material essence; the worshipers are free to gorge themselves on its material substance. As civilization advances, feasts or festivals (which are synonymous terms) generally increase in number, become elaborated ritually and more precisely fixed in the time and order of their celebration. It becomes the business of the priesthood to establish and maintain a calendar of sacred seasons in accordance with the natural divisions of the year. The observance of such holy days moreover contributes directly to the well being and prestige of the sacerdotal order.

Other holy days are fasts, marked not only by the cessation of ordinary activities but also by abstinence from food and drink and from sexual intercourse. At such times public gatherings may be discontinued, settlements closed or quarantined against outsiders, fires and lights

extinguished and songs, dances and loud noises forbidden. Fast days thus become times of almost complete quiescence, in striking contrast to feast days with their dances and processions, their sports, games and merrymakings and their generally Saturnalian aspect. The negative regulations for fast days are really tabus to be assimilated to the other restrictions and prohibitions which form so characteristic a feature of primitive society.

Feast days and fast days are found among the rudest known peoples, even migratory hunting, fishing and herding folk. They are especially characteristic of the agricultural economy, which implies a settled life, a more or less developed form of social organization and government, a definite priesthood and something approaching a calendar system. Many agricultural peoples also have market days, coming at frequent intervals and usually observed by a cessation of labor except that involved in buying and selling. A market day is necessarily more or less of a holiday, affording opportunities for social intercourse, sports and amusements of all sorts. Sometimes it is regarded as unsuitable for farm labor and the ordinary occupations and is hedged about with various restrictions. The development in the direction of Sabbatarianism seems to be largely confined to the African Negroes.

The occasions calling for the imposition of communal tabus are almost innumerable. In general, any time of storm and stress will necessitate the imposition of a season of abstinence and quiescence. Tabu periods are declared therefore because of such unusual and consequently critical events as a conflagration, an epidemic sickness or an earthquake; after a death; at the changes of the moon; at the end of the old year and the beginning of the new year; during a time devoted to the banning of ghosts and demons; and in connection with such important undertakings as the commencement of a war, seed planting and harvest and the celebration of a solemn religious or magical ceremony. One observer, describing this custom among certain tribes of Assam, remarks that there is no end to the reasons for which a *kennie*, or general holiday, might be declared; and as no work is then done, the Assamese Sabbath seems to be a rather popular institution. On the other hand, the Sabbatarian regulations in old Hawaii had little of a holiday character. At such times a general gloom and silence pervaded the whole district or island. Every fire and light was extinguished; canoes were not launched; no person

bathed; and no one was to be seen out of doors except those whose presence was required at the temple. Even the lower creation felt the rigor of the law: the mouths of dogs and pigs were tied up and fowls were put under a calabash or had a piece of cloth fastened over their eyes in order that no unseemly sound might disturb the silence of the holy day. It is quite significant that the strict Sunday laws which the first missionaries introduced into the Hawaiian Islands met no opposition on the part of the natives. Sunday seemed very familiar to them; they even called it *la tabu*, the tabued day. All the regulations for the observance of tabu periods, however vexatious and burdensome, are cheerfully and gladly borne. They represent a kind of folk technique which has been adopted for the avoidance of possible pollution and for the propitiation of spiritual "power" or "powers." The consciousness that all precautions have been taken is itself invigorating; the community goes forward henceforth with renewed strength and confidence to the tasks which lie before it.

No clear line of demarcation can be drawn between these tabu periods and the unlucky periods so commonly found among peoples of archaic culture and still surviving, although often in attenuated form, in modern civilized lands. Both involve ideas of contagion, the danger or pollution which attaches to the former being regarded as scarcely less transmissible than the vaguer "unluckiness" which belongs to certain times and seasons and affects everything done during their continuance. The same precautions and prohibitions characterize them: not to work; not to travel; not to buy and sell; not to use fire and lights; not to make loud noises; not to indulge in food or in sexual intercourse—all the familiar tabus. Unlucky periods are often institutionalized; that is, are taken up into the social framework, dedicated to the gods and made of general religious obligation. It is along these lines that one must seek the origin of many Sabbatarian observances. The ancient Babylonians kept every seventh day of the lunar month as an "evil day," in addition to the nineteenth day, which was regarded as seven times the seventh day (i.e. the forty-ninth day from the first of the preceding month). These were occasions for fasting, cessation of business and other forms of abstinence. The Hebrews seem to have held their Sabbaths at new moon and full moon long before the introduction of the weekly Sabbath on the seventh day. The Pentateuchal codes contain abundant evidence that in both its ear-

lier and its later form the Sabbath was invested with prohibitions which can only be interpreted as tabus. The time came when the exaggerations of Pharisaic Judaism led to the enumeration of no less than thirty-nine classes of prohibited actions on the holy day. Primitive Christians for a time continued to observe the Sabbath; this practise met the unqualified condemnation of St. Paul and of the early church fathers and ultimately disappeared. Sunday, or to use its ecclesiastical designation, the Lord's Day, was not at first a time of restrictions and prohibitions; but from the fourth century onward the view that the Christian Lord's Day was but the Jewish Sabbath transferred from the seventh to the first day of the week found occasional expression in both the law and the theology of the Middle Ages, culminating in the Sabbatarian excesses of English and Scottish Puritanism. The Buddhist *Uposatha*, which usually falls on the days of the new moon and the full moon and on the two days which are the eighth from the new moon and from the full moon, is marked by fasting and continence and in many cases by the suspension of both public and private business. The *Uposatha* was one of the earliest institutions of Buddhism; in its origin it owed nothing to Jewish or Christian influence; and its diffusion throughout southeastern Asia seems to have been unaffected by the influence of Islam. The Arabs themselves, who adopted the seven-day week from Jews and Christians, presumably at the time of their conversion to Islam, observe *al Jum'a*, "the meeting" (for worship), on Friday. According to Mohammed's injunction the faithful are to attend the mosques on this day. Labor is suspended during the service; but at its close secular vocations, including marketing, are resumed. The Moslem Day of Assembly is therefore not a holiday, nor is it characterized by restrictions and prohibitions. In the new Turkey of Mustafa Kemal, however, the day is now kept very much as the so-called continental Sunday in Europe, and possibly this reform will be introduced into other eastern lands.

The religious element in feasts and fasts becomes with the passage of time less and less pronounced: what began as a holy day ends as a holiday. This applies particularly to seasonal festivals, but even those of an anniversary character will lose their religious significance as the events commemorated by them recede into the distant past. Sometimes the holy day disappears altogether. The Protestant Reformation, where

it succeeded, abolished the majority of Roman Catholic saints' days, and the Russian Revolution has done the same with those observed by the Orthodox church. An industrialized world must, however, make some compulsory provision for social relaxation, so that Sunday legislation and the regulation of work periods and hours of labor seem likely to appear more and more on the agenda of the paternalistic state.

HOLLAND, HENRY SCOTT (1847-1918), English reformer. Holland was an influential force in converting the leaders of the Church of England to the belief that a social question existed and that Christianity has a message for corporate life as well as for the individual soul. He was a leading member of the group of English clergy who in *Lux mundi* (ed. by Charles Gore, London 1889) carried the Christian apologetic to a new stage: they ceased to stand on the defensive against modern thought and found there a vehicle for Christian and specifically for Anglo-Catholic doctrine. He was canon of St. Paul's from 1884 to 1910 and regius professor of divinity at Oxford from 1910 until his death. Holland carried on his social reform work through the Christian Social Union, of which he was one of the founders, and the *Commonwealth*, a monthly magazine which he established and edited. He was active in interpreting the church and the labor movement to one another. Liberal rather than collectivist in his convictions, Holland never identified himself with socialism; for this very reason he was the better able to induce conservative church opinion to consider social idealism and social reform. He contributed much to the development of the friendly relations which prevail between church and labor in England in contrast to the enmity on the continent.

HOLLAND, SIR THOMAS ERSKINE (1835-1926), English jurist. Holland held the chair of international law at the University of Oxford from 1874 to 1910. His most important work is his *Elements of Jurisprudence* (Oxford 1880, 13th ed. 1924), perhaps the best exposition of the doctrines of the English school of analytical jurisprudence founded by Austin, to whose work, however, it is superior in clarity and consistency. It attempts to construct a formal science of positive law based, as Holland said, on "those comparatively few and simple ideas which underlie the infinite variety of legal rules." Its weakness lies not in the execution of the design but in the conception, for the political and legal phenomena which the book analyzes are probably less simple than Holland supposed. The book has been influential in sustaining the Austinian tradition. In international law Holland did valuable work in editing three classics of historical importance, the *De jure belli* of Gentili, the *Jus et judicium feciale* of Zouche and the *Tractatus de bello, de represaliis, et de duello* of Legnano. He was also a publicist in international law, and his exposition of a complicated question or his criticism of an official policy was often influential in guiding public opinion; but, as in his juristic theorizing, he had a tendency to give his conclusions too great an air of finality.

Consult: Holland, T. E., *A Valedictory Retrospect* (Oxford 1910); Holdsworth, W. S., in *Proceedings of the British Academy*, vol. xii (1926) 317-26; Higgins, A. P., and Brierly, J. L., in *Law Quarterly Review*, vol. xlii (1926) 471-77.

HOLST, HERMANN EDUARD VON (1841-1904), German-American historian. Von Holst was born in Russia of German parentage but soon after taking his degree at Heidelberg came to America and began a study of American institutions. Returning to Germany in 1872 he entered upon his academic career, which took him first to Strasbourg, soon afterward to Freiburg and finally in 1892 to the University of Chicago. His monumental series, usually referred to as *The Constitutional and Political History of the United States*, was written originally in German and with the appearance of the successive volumes was translated into English. Although state sovereignty and the movements threatening disintegration of the union receive critical attention, Holst made no attempt to present a systematic study of either constitutional development or democracy. His sym-
pa-

thies were engaged in the struggle for national integrity and extirpation of slavery. He entered the lists as a combatant for the right as he conceived the right to be; with learning, ability and toil he championed a moral cause. His pages are heavily documented; although no slave of inhibiting objectivity he does not indulge in mere diatribe. For an understanding of his work it is necessary to remember his inborn hatred of Russian autocracy and his associations with Germany and German historians during the twenty years of his active productive scholarship. As a liberal, deeply interested in the integration of the German nation, he found in America a theme worthy of devoted attention. Von Holst's next most important work was his *John C. Calhoun* (Boston 1882), an able and not unfair presentation of the life of a man whose doctrines the author particularly condemned. He also wrote *The French Revolution Tested by Mirabeau's Career* (2 vols., Chicago 1894), *John Brown* (Boston 1888) and *Das Staatsrecht der Vereinigten Staaten von Amerika* (Freiburg i.Br. 1885, tr. by A. B. Mason, Chicago 1887).

HOLSTEIN, FRIEDRICH VON (1837-1909), German statesman. After a diplomatic apprenticeship of eighteen years, during which he served as a trusted lieutenant in forwarding Bismarck's foreign policy, Holstein in 1878 was appointed ministerial councilor. Although his titular rank was repeatedly raised, he continued to act in this capacity until his retirement from public office in 1906. Virtually unknown to the public, Holstein dominated German foreign policy for a decade and a half. Endowed with an extraordinary capacity for work and an uncontrollable hunger for power but shrinking from responsibility in public, he came to display in the secretive conduct of his office an almost pathological suspiciousness and obstinacy. But he was able by reason of his shrewd and expert knowledge to play his eccentric role, until during the first Moroccan crisis in 1905 Maximilian Harden's exposure of his dangerous intrigues resulted in his dismissal during Bülow's illness. Although he obtained his position as an adherent of Prince Bismarck and was a friend of the latter's son Herbert, Holstein played a large part in the chancellor's fall. In addition to personal reasons for so doing the question of the renewal or lapse of the so-called reinsurance treaty with

Russia was of considerable significance. It is primarily due to Holstein that at that time (1890) Germany abandoned its friendly alignment with Russia, which then finally turned toward France. He was an active exponent of the "new course" and of the "policy of the free hand," and although he had some measure of success in this endeavor to obtain overseas possessions he manoeuvred Germany into a position of perilous isolation. While recent research has proved that Holstein was not the chief cause for the failure of the Anglo-German alliance negotiations at the turn of the century, the unfavorable consequences for Germany of the Moroccan crisis in 1905-06 were due to the contradiction between Holstein's policy of readiness for bellicose conflict and the pacific disposition of the emperor William.

HOLT, SIR JOHN (1642-1710), lord chief justice of the King's Bench. His childhood witnessed the passing of legislative power to Parliament and his careless youth coincided with a period of radical legislative change, including the abolition of military tenure. In the year of the Restoration he entered Gray's Inn. When called to the bar three years later he found the political intrigues of the day reflected in a disgraceful series of state trials and he became a conspicuous counselor of defendants. Appointed to the recordership of London in 1686 he lost it for resisting the royal view of military law. In the Convention Parliament he advocated the use of the word abdication instead of the milder desertion with reference to the king's conduct. Shortly thereafter he was elevated to the chief justiceship, and he held the office almost until his death.

As chief justice Holt did a great deal to infuse a new spirit into criminal procedures. He distinguished himself by impartiality in state cases, kindness to prisoners (in contrast with his notorious predecessors), bravery in facing both the populace and the military authorities in scenes of disorder, enlightenment in ending the witch-

craft prosecutions and most of all quiet dignity in defying both houses of Parliament when they sought to interfere with the judicial prerogative in election and peerage cases.

Holt's influence was even more profound upon English commercial law. In his day commerce had passed into the hands of ordinary Englishmen and special courts for mercantile law had declined. He met the situation by taking judicial notice of the law merchant as part of the *jus gentium*. To one who claimed exemption from it as a gentleman he replied that whoever draws a bill becomes a trader. Yet he resisted the dictation of Lombardy Street: a statute was required to place promissory notes on the basis of bills of exchange. His remarkable dictum in *Coggs v. Bernard* (2 Ld. Raym. 909), a veritable treatise on bailments, takes its nomenclature from Roman law but its substance comes from the fruitful English doctrine of implied contract. In other cases he laid the foundation for the master's liability for servants' acts.

HOLTZENDORFF, FRANZ VON (1829-89), German jurist and publicist. Holtzendorff was professor at Berlin and later at Munich, but he was no dry pedant; on the other hand, throughout his extraordinarily varied and active participation in public affairs he always remained the man of science. A middle class liberal of the old idealistic type, he nevertheless exhibited strong social tendencies. As a liberal Protestant he resisted the orthodox tendencies of Wichern and worked in the Protestantverein. Although an adherent of Bismarck he opposed the latter in his controversy with Count Arnim in 1874. Holtzendorff as a jurist contributed to penal law, penology, international law and political science. In these fields he organized what was then a new form of juristic literature, a series of handbooks of great value issued under his direction. Holtzendorff always stood for progress. As a penologist he was against the death penalty; as early as 1859 he demanded the intro-

duction of the progressive Irish penal system now adopted almost everywhere; he also fought against the subordination of the public prosecutor to the Ministry of Justice. As an internationalist he worked for a world community and the cooperation of the peoples; he thus won many friends, among them Lieber, Cobden, Rivier, Jacquemys, Carrara and Mancini. He brought many foreign developments to the knowledge of German readers and translated many foreign works. He had great success as a social reformer in his campaigns for popular education, the care of the poor and the improvement of the position of women. To further popular education he published with Virchow the *Sammlung gemeinverständlicher wissenschaftlicher Vorträge* (1866-1901), with Oncken the *Deutsche Zeit- und Streitfragen* (1872-93). In political science he was interested particularly in the problem of public opinion. Holtzendorff was a brilliant orator and he proved a great stimulating force. A man of high moral and intellectual qualities, he worked for his aims with untiring energy and laid many of the foundations for future progress.

HOLY ALLIANCE. The Holy Alliance was a name popularly applied to the attempt to organize a new system of international relations at the close of the Napoleonic wars. It was really applicable only to one part of the whole and that not the most important, but the adoption of the phrase by historians who never investigated the facts has perpetuated the misunderstanding.

The system of the alliances set up by treaties and other documents in 1814-15 can in fact be divided into six different conceptions.

The Quadruple Alliance was made between the four great powers who led the coalition against France—Britain, Russia, Austria and Prussia. First signed at Chaumont on March 1, 1814, it was revived at Vienna on March 25, 1815, after the return of Napoleon and finally reconstituted at Paris on November 20, 1815. Initiated by the British foreign minister, Castlereagh (*q.v.*), it bound the four powers together in mutual support, with specific numbers of troops, against French aggression if France should violate the new frontier just set up at Paris. Moreover, it would come into force if Napoleon or any of his family should ascend the throne of France, since French aggression was considered certain to be the result of such an event. A third possibility was that of using the alliance should a revolution break out in France. This treaty was reaffirmed at the Conference of Aix-la-Chapelle in 1818 after the army of occupation had been removed from France and as late as 1840 was not without influence on international events.

In 1804-05 in negotiations between Britain and Russia proposals were made to guarantee all the frontiers of Europe by the armed force of all the European states. This scheme was also proposed by Castlereagh at the Congress of Vienna in February, 1815. Accepted in principle by Alexander I of Russia, it failed to come into force not only because of a proposal to include the Ottoman dominions but also because of the return of Napoleon from Elba. Subsequently Britain opposed it at the second peace of Paris, but the idea was revived in a modified form by Prussia at the Conference of Aix-la-Chapelle in 1818 and again rejected by British influence. On other occasions in the nineteenth century the proposal recurred but was never accepted.

A third category was that connected with proposals for alliance as a protection against revolution. In the treaty of November 20, 1815, it was laid down that if a revolution should break out in France the four powers would meet together to consider whether action was necessary. The czar wished to guarantee Louis XVIII and his family on the throne of France, but Britain could not sign such a treaty: even in 1792-93 it had refused to fight the French Revolution as such. But the continental autocrats later wished to develop this aspect of the alliance. At

Aix-la-Chapelle the czar proposed a treaty guaranteeing all the thrones and frontiers of Europe. Castlereagh easily prevented the acceptance of this project and also the interference of the alliance when the Spanish revolution broke out in January, 1820. But after the Neapolitan revolution of July, 1820, Metternich, the Austrian chancellor, went over to Alexander's point of view, and at the conferences of Troppau and Laibach in 1820 and 1821 the three eastern powers affirmed that the alliance had the right to put down revolutions. Castlereagh protested both privately and publicly on January 19, 1821, against this unwarrantable extension of the treaty. But the revolutions of Naples and Piedmont were repressed by Austrian forces acting as an agent of the alliance. Subsequently, after the conference at Vienna in 1822, the Spanish revolution was put down by France acting in a similar way. It was these actions which caused liberals to use the term Holy Alliance as one of reproach for the whole system of the alliance, caused Britain under Canning to withdraw from its continental associations and led to the position which the United States took up by the declaration of the Monroe Doctrine after Britain had shown it would not allow the same process to be applied to the South American revolutions.

The most novel part of the whole system was the idea of diplomacy by conference introduced by Castlereagh into the treaty of November, 1815. This was simply an agreement by the four powers that the principal sovereigns and statesmen should meet together at intervals to discuss international problems. Castlereagh obtained the idea as a result of the experience of 1814-15, when the sovereigns and statesmen constituted a supreme council to manage the war against Napoleon; Castlereagh represented Britain on this council from January, 1814. The most notable application of the idea was at the Conference of Aix-la-Chapelle, which terminated the occupation of France and finally settled the question of reparations. By a special declaration France was admitted to the system of conferences on equal terms and the term Quintuple Alliance was therefore afterward sometimes used. This conference also dealt with other diplomatic questions involving the rights of smaller powers. The great powers recognized, however, the delicacy of their position and by a special protocol agreed that small powers should be summoned to their meetings if their interests were discussed. This protocol was referred to later in the nineteenth century in connection with later ambas-

sadorial conferences but was often disregarded. As has been seen, the system of diplomacy by conference had been used by the eastern powers to repress the revolutions in southern Europe and was thus discredited; Castlereagh hoped to restore it by his presence at the Conference of Verona in 1822, the last of the conferences, but his suicide resulted in the prevalence of reactionary doctrines there and Britain's withdrawal meant the end of the system. Without Britain's mediating influence the continental powers soon became estranged and the meetings ceased, except for an abortive conference at St. Petersburg to discuss the Greek revolution in 1825, at which Britain refused to be represented. The importance of Castlereagh's scheme was thus obscured by the use to which it was put, and he failed to win public opinion for its support. The smaller powers were suspicious of it as they had no place in it, and it was difficult to carry out systematically with the means of communication and transport then available. It was, however, the first attempt to organize a system which, it has since been recognized, is indispensable to the conduct of international relations.

There were also set up in 1815 ambassadorial conferences of the great powers at Paris, London and Frankfort. Of these that at Paris, which dealt with the post-war problems of France, such as the army of occupation and reparations, was the most important, being a kind of subordinate executive of the Quadruple Alliance. Other problems were also referred to it for settlement. But after 1818 Britain insisted it should be dissolved and later attempts by the continental powers to revive it between 1823 and 1825 failed. The London Conference designed to organize the abolition of the slave trade and that at Frankfort for German problems were even more temporary. These conferences may, however, be considered as the models of the many special ambassadorial conferences of the nineteenth century, which were later often considered as an expression of the Concert of Europe. In this inferior form and only spasmodically the system of diplomacy by conference survived; it was to this form of conference that Grey vainly appealed in 1914.

Lastly, there was the treaty of the Holy Alliance of September 26, 1815. This was entirely due to the czar, Alexander, who during this year became obsessed with religious exaltation to such a degree as to be mentally deranged. He had for some time been in close communion with devotees of Pietistic religion, although he remained

faithful to the Greek Orthodox church; one of the votaries of the former sect, Madame de Krüdener, gained access to him after the return of Napoleon and for a short period had a considerable influence over him. Although he claimed that it was inspired by Castlereagh's proposal at Vienna for a general territorial guaranty, the treaty was no more than a promise by the sovereigns who signed it to act toward one another and toward their subjects in accordance with the Christian faith. As such it was entirely harmless, since there was no definition of such conduct and no penalties or sanctions were laid down. All the sovereigns of Europe except three therefore eventually signed it. The prince regent, later George IV, could not do so for constitutional reasons, although he sent a letter intimating his agreement; the pope could not sign for religious reasons, nor could the sultan because he was not a Christian. When it was published in 1816 this last fact made some insist that it was part of a Russian design against the Turk, but there is no foundation for the suspicion. The importance of the treaty lies in the fact that its unusual and dramatic character caused the Holy Alliance, as has been pointed out, to be used as a term for the other more practical proposals. Alexander himself always attached the greatest importance to it, and even made some effort to associate the republics of Switzerland and the United States with it. But its influence died with him, although the term Holy Alliance was in the 1830's applied to the association of the three eastern autocrats in opposition to the more democratic western powers of Europe.

HOLY PLACES. The Romans drew a distinction between *loca sacra*, or places made over to religious use by an act of dedication, and *loca religiosa*, or sites affected by tabus in consequence of some supernatural occurrence. In

many instances the two coincide. The events of religious tradition are usually commemorated by shrines, temples or churches on the spots where they are supposed to have taken place. Catholic churches were until recent times not regarded as adequately consecrated unless they could point to the possession of the body of a saint or a holy relic or to some tradition, miraculous vision or theophany hallowing the place on which they were erected. Similarly, sacred or tabued sites where magico-religious rites were held abounded in primitive cultures. The selection of the locality was often accounted for by some aetiological myth.

Certain spots may be regarded with special awe as being the haunts of supernatural beings—the ghosts of the departed or the spirits of the unborn. Burial places and sepulchers are thus commonly hallowed, and many holy places derive their sanctity from the circumstance that they are held to be tombs of powerful personages: heroes, saints or gods. Among the Bushmen, for instance, mounds of stones erected throughout the country were given out to be the tombs of Heitsi-sibib, a supernatural being who was believed to suffer a monthly death and to rise again after the third day of the interlunar period. Similarly, ancient Egypt possessed several tombs of Osiris. Greece and western Asia abounded in similar holy sepulchers. In the Delphic shrine was the tomb of Dionysus, regarded as the omphalos, or center, of the world; in Crete the sepulcher of Zeus, at Tyre the sepulcher of Dagon.

The locality of sacred places is often determined by natural features. Caves and grottoes have been almost universally regarded as sacred. The painted caves of the Magdalenian period in northern Spain and southern France, the caves of Zeus in Crete, the countless oracular caves of Greece and southern Italy, the holy cave of Delos—the mythical site of the nativity of Apollo—the grotto of Pan on the Athenian Acropolis, the grottoes of Adonis or Tammuz in Cyprus and Syria, illustrate the widespread prevalence of sacred caves. Sacred springs, lakes and rivers are no less abundant, as are likewise consecrated groves. Mountain tops have commonly been regarded, notably in western Asia and Europe, as the dwelling places of the gods and have been the natural sites of sanctuaries. On the alluvial plains of Mesopotamia the earliest temples constructed on a monumental scale, the Sumerian and Babylonian zikkurats, were probably designed to represent the hilltops, or

“high places,” on which the ancestors of immigrants from Elam and Iran had been wont to celebrate their rites.

The sacred enclosure, or *hima*, corresponding with the Greek *temenos*, was among the early Semites marked off by erect stones or pillars. Access to the sacred ground is usually restricted by certain qualifications. Sometimes, as in the case of the Polynesian *marai*, the precinct is forbidden to women, while at other times, as in many African and ancient Greek agricultural cults and the Roman rites of *Bona Dea*, it is forbidden to men. Entrance to the sacred precinct requires that certain conditions necessary to the state of ritual purity shall have been complied with, so that the visitor may not incur the wrath of the god.

The Babylonian high places, protected by a fortified enclosure where people and cattle might seek safety in the event of raids and attacks, constituted cities of refuge and formed the nuclei of cities. Temples and sacred places have in like manner frequently determined the sites of towns, which have grown around the sanctuaries. While the god is held to afford protection against the attacks of enemies, he is also deemed to assume responsibility for the fugitive or criminal who seeks refuge in the sanctuary. The resulting right of asylum, although it doubtless prevented hasty retribution, at all times led to abuses which caused it to be disregarded. It was abolished in Rome by an edict of the emperor Tiberius except in the temples of Juno and of Aesculapius. Under Constantine and Theodosius the right of sanctuary was bestowed upon all Christian churches and their dependent buildings. The right was greatly abused throughout the Middle Ages and was abolished in England in the sixteenth century.

The sacred character of holy places commonly outlasts the cults and religions under whose auspices they have been dedicated. Thus the cave of Adonis at Bethlehem became transferred to Christian use as the grotto of the Nativity. The Vatican, or hill of divination, at Rome, where in early times omens were interpreted by the college of pontiffs, was in late imperial days consecrated to the cult of Mithras and became at length the see of the supreme pontiff of the Catholic church. The Celtic shrine of Lugh became during the Roman occupation of Britain a temple of Diana and later St. Paul's Cathedral. The ancient Arabian sanctuary of the Caaba at Mecca was retained by Islam as the most holy place of the new religion. Greek, Roman and

Celtic temples have been transformed into Christian churches; in Spain mosques have become Catholic cathedrals and conversely Christian churches, such as St. Sophia in Constantinople, have been transformed into mosques.

The lucrative value of holy places has led from earliest times to competition between rival sanctuaries. The interests of the priests of the old Jebusite sanctuary of Jerusalem and their jealousy of the numerous shrines which diverted sacrifices, tithes and first fruits doubtless motivated the destruction of rival places of worship throughout Israel and Judea, especially under the leadership of King Josiah. The dispensing of special graces and indulgences to the worshiper at prescribed shrines led, with the territorial expansion of institutionalized religions, to the development of pilgrimages which became the source of enormous traffic and local wealth. The Arabian hadj, or holy pilgrimage, is a primitive Semitic institution much older than Islam. In India numerous holy places are the objectives of pilgrims, who gather from distant parts of the country. The chief of these is the holy city of Benares, to which both Hindu and Buddhist resort in order to bathe from the numerous ghats, or holy stairs, in the waters of the Ganges. Buddhists congregate in addition in the holy places of Kapilavastu, Gaya and Kuśīngara, associated by tradition respectively with the birth, vocation and death of Gotama Śākya-muni. During the Middle Ages in Europe pilgrimages to reputed shrines assumed enormous proportions. In England the most popular resorts were Glastonbury, an important Celtic holy site converted to Christian use, and the see of Canterbury, sanctified by the martyrdom of Thomas à Becket. The holy well of St. Winifred in Flintshire and Lough Derg, or St. Patrick's Purgatory, in Donegal, were also ancient pagan holy places which, some complained, were shamefully exploited by the local religious houses. So likewise was the holy grotto of Chartres in France, where an ancient Celtic wooden statue of a goddess bearing the holy infant in her arms had become a miraculous Madonna. The shrine of Santiago of Compostela in Spain, where according to a priest's vision, the body of the apostle James was buried, drew from the twelfth to the eighteenth century enormous crowds of pilgrims from every part of Europe. In Italy the holy house of Loreto, the reputed home of the Virgin miraculously transported from Palestine, and the shrine of St. Anthony at Padua were the most popular. The Holy Roman See spared no effort to draw the

devotion of the faithful, divided among so many shrines, to Rome as the capital of Christendom. The popularity of the pilgrimage to Rome reached its height with the jubilee of Pope Boniface VIII in the year 1300.

Since the time of Constantine pilgrims have flocked to Palestine to worship at the traditional spots where the events of sacred history were reputed to have taken place. The house of Dives and the spot where the beggar Lazarus had stood, the home to which the prodigal son returned, the well where Christ had spoken to the Samaritan woman, the scene of the assumption of the Virgin and her tomb were all designated. Place names mentioned in the Gospel narrative, such as Golgotha, Gethsemane, Nazareth, which baffle the researches of the historical geographer, were assigned to gratify the pious curiosity of devout visitors. After the conquest of Palestine by Islam the Greek priests and monks remained for the most part undisturbed, and Christian pilgrims continued to flock in ever increasing numbers to the Holy Land, unmolested by the Arab authorities. The Catholic church used the popular eagerness to visit the holy sites of Christian tradition as a means of combating the power of Islam, which had threatened to overwhelm Christendom during the Dark Ages. The crusades were moved with the overt object of liberating the holy places of the Christian religion from Arab domination. The long and disastrous struggle led for a period to the establishment of the Latin kingdom of Jerusalem. The French, who had borne the chief part in the conflict and had provided the new rulers, retained, after the fall of the kingdom, a recognized right of jurisdiction over European pilgrims, which continued to be exercised and acknowledged when Palestine passed under Turkish rule. That traditionally established right constituted the basis of the Capitulations, which were first officially established under that name by the accord concluded in 1535 between King Francis I and Sultan Suleyman II. Similar agreements bestowing upon European governments the right of jurisdiction over their nationals and over the religious foundations established by them in Palestine were obtained by England in 1583, by Spain in 1782 and by Russia in 1783. The favored position of France as chief protector of the religious houses in the Near East was confirmed in 1740 by the treaty of Belgrade.

Under Turkish rule the difficult task of maintaining order among the various denominations claiming a share of the holy places in Palestine

was carried out with impartial tolerance. The various European governments, however, lost no opportunity of using the professed religious interests to further their political ends. The disputes and friction between the Orthodox Greek church, the Armenian church and the various Protestant bodies were bitter and prolonged and the Turkish authorities were frequently called upon to intervene to restrain the mobs of pilgrims of various denominations from bloody conflict. The Greek Orthodox priesthood enjoyed in most instances the right of first possession and had in its keeping the key to the Holy Sepulcher. Difficulties arising out of Catholic claims to right of way were resolved at the Church of the Holy Nativity by the construction of subterranean passages and chapels under the Greek construction. The ancient claims of France to supreme jurisdiction over the Christian foundations in the East, reasserted by Emperor Louis Napoleon as against Czar Nicholas' claim to independent protectorate over the Greek church, served as a pretext for the Crimean War. Russia continued until the last days of czarism to send pilgrims by the thousand to the holy places and repeatedly strove to enlarge its sphere of influence and to make its protectorate over the Orthodox bodies paramount. The huge Russian church, surrounded by countless buildings and dominating Jerusalem, formed a veritable fortress so threatening in character that it was at once dismantled by the Turks on the outbreak of war in 1914. The British mandate and the Balfour Declaration of 1917 giving sanction to the claims of the Zionists added a new source of religious and political conflict. The struggle over the right of the Jews to worship at the Wailing Wall at Jerusalem has been made an issue by Moslem religious leaders. They led the Arab population to believe that the Jews aimed at gaining possession of the Mosque of Omar, the site of the ancient temple. The dispute has led to clashes between Arabs and Jews and continues to be a source of acrimonious controversy.

HOLY ROMAN EMPIRE. The Holy Roman Empire was the western empire existing either as an effective power or as a formal entity from 800 to 1806. Its prototype was the Christian Roman Empire which had come into existence with the adoption of Christianity as a state religion following the conversion of Constantine. At that time church and empire had become united under the leadership of the emperor to administer the Augustinian kingdom of God. Both institutions prior to their coalescence as well as after were hedged about by a sacred aura of inevitability. The Roman Empire, embracing in fact the entire cultural world, was in theory universal; the pagans believed it to be eternal, an *imperium sine fine* according to the prophecy of Vergil; and after the establishment of the Christian empire St. Augustine identified it as the last of the four world monarchies described in Daniel's dream and the one which was to endure until the coming of Antichrist. The Christian church had more logical, less factitious support for its claims to universality and imperishability.

The barbarian invaders who poured into the Western Roman Empire in the fourth and fifth centuries at first remained under the spell of the Roman tradition. Even after the Western Empire had completely disappeared and its pretensions to universal authority had passed to Constantinople, which lacked the power to enforce them, a king of the Franks accepted the title of consul from the Eastern Empire. By the seventh and eighth centuries, however, the idea of the unity of the world under a Roman Christian em-

peror retained its vitality only within the church. Having preserved in its organization the deep impression of Roman laws and institutions the church was itself to a large extent Roman. The fact that the Eastern Empire was subject to the religious authority of the patriarch of Constantinople and that except in brief interludes it was inimical to the Western church gave impetus to the papal desire for emancipation from the east. In the eighth century there emerged in a process begun by Pepin and consummated by Charlemagne (742-814) a Carolingian kingdom of the Franks, which by virtue of its actual authority over almost all of Europe as well as by its assumption of the guardianship of the Holy See possessed the prerequisites for a revived empire of the west. Neither Pepin nor Charlemagne had any intention of linking himself to the past. But Pope Leo III took advantage of Charlemagne's position to thrust the sacred Roman tradition upon him at the Christmas celebration held at Rome in 800. By this act he liberated the papacy from the specter of the Eastern Empire, proclaiming the end of Byzantine domination in central Italy, and created a new empire of the Romans (not yet in title although it was in fact the Holy Roman Empire) as the palladium of the Western church.

There was now in existence a concrete organization which gave a semblance of reality to the political conceptions evolved by the church in the period when the old Western Empire was vanishing and preserved by it during the intervening centuries of chaos. At the basis of the doctrine was the assumption of one universal faith and of one coextensive political authority; in the same way that one God ruled the world one monarch, so it was inferred, must reign over the world, guaranteeing peace and justice. According to the refinement effected by Pope Gelasius I (d. 496) the relations of church and state were dualistic but interdependent. The universal pontiff held spiritual authority, the universal emperor temporal; but each derived directly from God and supported the other in the exercise of his functions. The papacy constituted the soul and the imperial power the body of the universal organism. This theory sometimes intact, sometimes in a modified form, for long centuries almost forgotten, clung to the Holy Roman Empire throughout its whole extent. No subsequent age, however, translated it into practise to the same degree as Charlemagne. Although he himself ruled the church as an absolute monarch he nevertheless established a harmonious reciproc-

ity between it and his vast empire and was guided by the vision of a "divine state." His system disappeared with the rapid decay of the Carolingian power and the segmentation of the realm after his death, but the tradition he created was a powerful influence in determining the continued existence of the empire.

It was not until 962 that the title of Holy Roman emperor became again vested in an effective monarch, the German king Otto I (912-73). This event signified less a prolongation of Charlemagne's empire than its reestablishment on a modified basis. Otto's claim to the Roman crown arose from his control of the strongest military and political power of his time; his empire held a position of hegemony in Europe because of the superiority of Germany to other powers. But he lacked the actual jurisdiction over Christian Europe which had given reality to Charlemagne's title. The sphere of substantial authority possessed by Otto and his successors included Germany in the vast extent of that time (but at first no farther east than the Elbe-Saale line and Lower Austria), northern and central Italy and after 1032 Burgundy as far south as Arles. They exercised also limited sovereignty over the still uncivilized states on the empire's borders—Denmark, Poland, Bohemia, Moravia and for a time Hungary. Theoretically the emperor remained a world monarch reigning over all kingdoms, the temporal representative of God guaranteeing world peace. In reality the emperor was first of all a German king endowed with the incidental dignity of *romano-rum imperator augustus*, which he acquired by journeying to Rome for coronation by the pope. With the exception of Otto III (980-1002), who in his almost mystical obsession with the cult of *Roma aeterna* made a utopian attempt to transfer the seat of government from German soil to the nominal capital, Rome, the emperors governed through the German administrative machinery; Burgundy and Italy they left to their feudal vassals—bishops or laymen—resorting to personal interference only on transient occasions. They controlled papal elections and were themselves received into the spiritual hierarchy through ordination as deacon. Not merely in theory but to a certain extent in practise it remained their supreme function to defend the church against heresy and disobedience within and to convert the heathen without. Nevertheless, the intimate union of church and empire had ceased to be a fact. In its place appeared a duality of interest, at first merely implicit because the emperor dom-

inated the pope, but already presaging later rivalry.

The empire endured on the lines marked out by Otto I until the death of Henry III (1017-56). Thereign of his successor, Henry IV (1050-1106), marks the beginning of the period of struggles with the papacy. In the first phase of the conflict, known as the investiture conflict (*q.v.*) and lasting from 1075 until the Concordat of Worms in 1122, the reforming papacy under Gregory VII and later popes so far succeeded in reversing its previous position of subservience that it was able to undermine the control of the emperors over the bishops, to assert as a working principle the supremacy of the spiritual power over the temporal and in the first crusade of 1096 to assume the actual leadership of Christianity. The first phase ended, however, with a compromise as to the specific question which had evoked it and with the broader question as to the relation of the two powers still unsettled.

Precisely thirty years after the concordat Frederick Barbarossa (*c.* 1125-90) inaugurated the reign of the Hohenstaufen line, during which the empire rose to its last great height of solid power and self-assertiveness. The revival of Roman law at the time, resurrecting in all its sacredness the traditions of the late Roman Empire and sanctifying the secular state, conferred upon the Hohenstaufens a magnificent dignity which aided them vastly in their struggles against the papacy as well as in their assumption of new prerogatives in affairs of state. "The emperor is a living law upon earth," declares a typical document of 1230; the word *sacrum* became for the first time subjoined to *imperium romanum*. A strong tendency toward increased centralized administration of the imperial territory, not unrelated to the new conception of government currently evolved from the Norman example, manifested itself. The emperor stepped outside his role as German king and with the aid of his officials achieved the complete subjugation of the Italian cities. The evolution of a more rigid feudal law made it possible for the empire not only to reabsorb the German episcopate into its service but to establish a suzerainty over states outside its boundaries—under Henry VI even over Richard the Lion Heart and his Anglo-Norman realm, over oriental kingdoms such as Cyprus and Armenia. As compensation for the loosening of its grip on all the neighboring territories to the north and southeast except Bohemia and Moravia it expanded with the German colonization across the Elbe-Saale line, which pro-

gressively developed after the middle of the twelfth century, as far as East Prussia and Livonia; in 1194 it acquired the rich and culturally advanced kingdom of Sicily and in 1229 the crown of Jerusalem. These concrete gains enabled the Hohenstaufens to revivify the conception of a world monarch and to confront the papacy with the doctrine of the equality of the two God given swords.

Almost as soon as it reached its height the empire began to decline. The initial cause was disunity in Germany growing out of the rise of the Guelph faction and eventuating during the regency following the early death of Henry VI (1165-97) in a Guelph-Hohenstaufen civil war. Frederick II (1194-1250) although he ranks with the great Barbarossa as a powerful personality was compelled to surrender the dominant influence in Germany, which was the mainstay of imperial authority, to the ecclesiastical and lay princes while he struggled with the pope and the Guelph cities in Italy. In the meantime the rising nations outside the empire had seized the opportunity to evince their complete independence of it. Under Innocent III the papacy had profited from the existence of two rival aspirants for the throne to grasp the right of examining their claims, of rendering the final decision and even of deposition. Innocent's successors pursued the decisive struggle to final victory. The long period of time (1250-1312) that elapsed between the death of Frederick II and a new imperial coronation at bottom signified that the Holy Roman Empire had lost its old hegemony of Europe.

That it continued to exist for more than five hundred years after this period was due partly to the strength of the tradition in which it was rooted, partly to its close connection with the German kingship. From the end of the thirteenth century until the time of Louis XIV and Napoleon France as well as other nations tried repeatedly to wrest the imperial dignity from its German incumbents, but without success. Even the efforts of the papacy under Boniface VIII to usurp the authority of the imperial office when it was vacant or to reduce it to abject servility when occupied culminated in a reaction in favor of the empire. With the cultural efflorescence in Italy in the fourteenth century a late glory was cast about the declining empire by the philosophical argument of Dante and the impassioned partisanship of Petrarch. But this transitory gleam disappeared when the men of the later Renaissance turned their attention to other ideals at the same time that the fall of the Eastern Em-

pire in 1453 and the discovery of America were destroying belief in the inevitability of the old outworn world order. Since the time of Henry VII (1269?-1313) the emperors had ceased to appoint imperial governors to Italy, and both Italy and Burgundy had become progressively detached from the empire. When Emperor Sigismund convoked the Council of Constance in 1414 to reform a debased and schismatic papacy he exercised for the last time the imperial prerogative in international affairs. By this date, despite the contrary interpretations of conservative jurists, the sovereignty of the empire was already limited to the territory north of the Alps. From 1442 on the phrase *nationis teutonicae* was appended to *sacrum imperium romanum*. A concomitant development was the dissolution of the ties with papacy. No emperor after Frederick III (1415-93) went to Rome for coronation, although in 1530 Charles V (1500-58) allowed the pope to crown him at Bologna. Beginning with Maximilian I (1459-1519) the German kings uncereemoniously took the title of elected emperor, soon abbreviated to emperor.

Within Germany the power of the emperor as German king had for centuries been undergoing a process of attenuation. The lavishing of dignities upon him had signified a corresponding augmentation of the pretensions and rights of the princes. After 1257 the previously established but often empty principle that the Germanic throne was elective became definitely operative, the electoral power being henceforth vested in seven dignitaries—the archbishops of Mainz, Treves and Cologne, the princes of the Palatinate, Saxony and Brandenburg, and the king of Bohemia—rather than in the vague aristocratic body. In 1356 in order to prevent the evils of conflict between rival aspirants Emperor Charles IV issued the Golden Bull regulating the mode of election; this document, which became the fundamental law of the land, consecrated the federal character of the German state. Even before this the electors had been accustomed through the *Wahlkapitulation*, as it was called, to make the king's election contingent upon his agreement to their selfish demands. When he wished to take action against a foreign adversary, even in a national cause such as the suppression of the Turkish menace, he was without means of levying the necessary resources from the military and financial strength of his nominal dominions.

The year 1437 begins the period, virtually unbroken until the final dissolution of the empire, of the possession of the crown by the Austrian

house of Hapsburg. Preoccupied with developing their dynastic power, quick to sacrifice national interests, if for instance an opportunity was offered them to obtain the thrones of Hungary and Bohemia, the Hapsburgs progressively widened the breach between the imperial power and the nation. All projects to build up a strong state foundered on this mutual antipathy. When toward the end of the fifteenth century the princes faced the problem of reforming the chaotic government they were interested only in increasing the power of the Imperial Diet, an assembly representing the constituent estates of the empire—electors, principalities, lords and cities—at the expense of the emperor. They created councils to insure justice, peace and a reliable system of taxation, but having no means of executing their decisions they necessarily failed. The threat only inspired the Hapsburgs to retaliate by increasing the competency of their Austrian institutions, particularly of the Imperial High Court of Justice. The Reformation crushed all hope of reconstruction of the empire on the old basis or of reform through union of the estates, which were henceforth permanently divided by religious barriers. By its principle of individual liberty of conscience, its attacks upon Romanism, its foundation of independent national churches, it shattered the preexisting theory of a world order founded on two universal institutions; German states previously controlled by churchmen became secularized; and the Catholic Hapsburgs found themselves reduced within the empire to the position of factional leaders. What territorial expansion and external strength resulted from the union with Spain under Charles V benefited them as a dynasty but had no effect on the empire. Twice, in 1546 and during the Thirty Years' War, they sought to force Catholicism and acquiescence in an absolutistic imperial policy upon the nation; they were frustrated by the princes, Catholic as well as Protestant, who had no hesitation in forming alliances with foreign states to defend their "liberty." In consequence of the chaotic condition of public affairs such important states as Prussia, Switzerland and the Netherlands had already seceded from an empire whose heads on the one hand appeared to them as aliens and on the other had no power to compel cohesion. After the religious Peace of Augsburg in 1555, which set the final seal on schism and imperial chaos, the once vast authority officially vested in the emperor was, apart from his power of life and death and his right of initiative and veto in the

Imperial Diet, limited to the administration of the new postal service, which however existed only in south Germany, and the insignificant *reservata*, such as the granting of titles of nobility and the legitimization of children.

By the seventeenth century the imperial office had become a mummy; the constitution a monstrosity, to use the term of Pufendorf, who expressed an almost universal sentiment; Germany the battle ground of neighboring states. The Peace of Westphalia, at which the empire as such was not even represented, signified the international recognition of this condition. Not only did it provide for considerable cessions of German territory to France and Sweden but by legalizing the free right of the princes to confederate even with foreign powers it left the empire in everything but name a league of the loosest type, composed of three hundred small principalities and sovereign territorial units. The Imperial Diet, although it survived and indeed after 1663 sat in permanence at Ratisbon, ceased to be attended by the princes and degenerated into a conference of diplomats engaged in endless disputes over questions of precedence and other trivialities.

Seventeenth and eighteenth century German literature with its ubiquitous satires of the empire reflects the final internal effect of the protracted lingering of an obsolete institution. Except in certain small or medium sized principalities of the south and west there no longer existed the consciousness of a German nation politically united. The larger states, like Brandenburg-Prussia, Hanover and Saxony, imitated the example which the Hapsburgs had set them in Austria, pursuing a particularistic, often overtly antinational, policy. In the eighteenth century Prussia under Frederick the Great won recognition as a great power both within the circle of the Germanies and in the larger European family of nations. But the only immediate result of this development was the creation of an equilibrium between two jealous German states, the new Prussia and the old Austria. Mere particularism evolved into a struggle for hegemony without being destroyed by it. The league which Frederick formed among the principal north German states in 1785 was no more than a military alliance to defeat the expansionist ambitions of the Hapsburg Joseph II.

The impact of the armies of the French Revolution and the Napoleonic era finally uprooted the empire. Napoleon claimed to be the true successor to Charlemagne. By taking the title of emperor, receiving consecration by the pope, as-

suming the role of protector of the church, designating his successor as the king of Rome and by many other devices he linked himself to the tradition of the first Holy Roman Empire. At the same time the last prop of the German imperial authority was removed by the extinction of nearly all the imperial cities and of the political power of the upper clergy as well as by the strengthening of the sovereign south German states. In 1805 the Hapsburg Francis II began to style himself "hereditary emperor of Austria." The following year, when the sixteen states, chiefly south German, of the new Confederation of the Rhine formally announced their withdrawal from the empire, he at last surrendered the burdensome crown of his ancestors.

When the overthrow of the Corsican in 1814-15 raised the problem of translating into a concrete plan of unification the intense national feeling which had developed in Germany since 1806 as a reaction against Germany's political degradation, many voices, among them those of Stein and Görres, were lifted in behalf of the re-establishment of the Holy Roman Empire. The ancient legend of the emperor sitting enchanted in his mountain but some day to return was resurrected and helped to promote the desired unity by furnishing a symbol which was enshrined in tradition and harmonious with the mediaevalistic temper of the time. What was actually created, however, was the Germanic Confederation (1815-66), in which unity was compromised with particularism and supremacy was divided between Austria and Prussia. Only after the rivalry of these two states had been decided by arms in 1866 was it possible to erect a German Empire on a new basis.

HOLYOAKE, GEORGE JACOB (1817-1906), British cooperator and journalist. Born of a working class family in Birmingham, Holyoake started work at the age of nine. He acquired a fairly good grounding in mathematics, science and logic at the Mechanics' Institution between 1833 and 1836 and joined successively the trade union, Owenite and Chartist movements. He received the most enduring impulse from Owenism, which apart from the construction of utopias consisted at that time of vigorous propaganda for secularism and cooperation or home colonization. From 1841 to 1846 he was an Owenite social missionary, and although moderate as compared to many secularists he served six months in prison for having spoken with "improper levity" of the Deity. He lectured in Yorkshire and Lancashire on home colonization and visited Rochdale, a center of Owenism and Chartism, a year before the founding of the store which was the primary cell of the consumers' cooperative movement. In 1846 after the final collapse of the last Owenite settlement in Britain Holyoake settled in London and thereafter engaged in the cooperative movement and all the Liberal political and international movements of the Mill-Gladstone era. In 1845 he took the road to sober middle class politics. Socialism was to him henceforth but a telescope for the survey of a far off land, while cooperation and copartnership with the self-help of labor were close at hand to create such conditions as would render charity as well as state protection superfluous. His political activity was directed toward bringing about a reconciliation between Liberalism and the working class. Characteristically in the last months of his life, when Labour became an independent parliamentary power, he worked in his constituency for the Liberal against the Labour candidate.

He published and edited several free thought and cooperative papers, the most successful of

which was the *Reasoner*, and published numerous pamphlets and books. To compose a good book was apparently beyond his capacity. Even his ambitious *History of Cooperation* is but a haphazard collection. He knew little of research nor did he possess the ability to synthesize, being essentially a journalist and a collector of materials. He interested the leading Liberals mainly as a working man who had acquired an education which enabled him to do good journalistic work and as an ex-Owenite and ex-Chartist zealously contending for self-help and cooperation as antidotes to revolutionary socialism and for the integration of the working class into the Liberal party.

HOME ECONOMICS is the generic term used chiefly in the United States to describe the subject of study formerly known as domestic science, domestic economy, household arts or the science of home making.

In Europe home economics has not developed as a separate field of study but is in the main subordinate to general education; in the United States, on the other hand, where the movement has grown rapidly since the beginning of the twentieth century, it occupies a distinctive place in the educational curriculum. It is found at every academic level—in the elementary school, high school and university, in colleges of agriculture and of liberal arts, in normal schools, in vocational and industrial training schools. The courses may be organized to form a part of the education of all women or as a specialized sequence serving the specific purposes of a smaller group.

No definition of home economics has yet been devised that would adequately describe either the varied objectives of those carrying on work under this name or the character of the subject matter with which they deal. Not only does the content of the home economics curriculum show a marked tendency to change from period to period, but there is great diversity from one academic level and type of school to another. In the elementary and high schools it may be hand-work and household arts; in the college it may be "an integration of scientific and social educa-

tion that utilizes as a medium and incentive the activities and interests that arise from home and family life"; in the normal schools and technical institutes it may be preparation for specific gainful employment.

The typical pattern of home economics instruction may be suggested by the definition given by the American Home Economics Association in its *Syllabus of Home Economics* prepared in 1913. "Home economics as a distinctive subject of instruction is the study of the economic, sanitary and aesthetic aspects of food, clothing and shelter as connected with their selection, preparation and use by the family in the home or by other groups of people." This statement is an interesting combination of what actually was and what was hoped for at the time. Home economics has given slight attention to the problem of shelter and little to the economic aspects of the production and consumption of food and clothing. Many curious anomalies in the development of the discipline of home economics are explained by the tendency—indicated in the phrase "their selection, . . . use by the family in the home or by other groups of people"—to make the commodity or service the real unit of study and to consider any problem or activity connected with it whether directly related to the family or not.

The three objectives that appear to have been paramount in determining the content and character of the courses in home economics now presented in the various types of schools are, first, the development of handicraft skills, especially in cooking, sewing and other household tasks; second, the development of managerial intelligence and capacity, especially in child care, time and money budgeting and market selection; and, finally, preparation for specific gainful employments, primarily teaching but also institutional management, the practise of dietetics and a variety of positions in businesses dealing with the ultimate consumer or with the products used in the home.

The place of home economics in the educational system of the United States is indicated by figures collected by the United States Bureau of Education. In 1928-29 there were 322 colleges and universities offering a four-year course in home economics leading to a bachelor's degree; 88 others offered courses but gave no degree; 84 junior colleges as well as 90 normal schools and teachers' colleges also reported courses. In 1928, 8072 public high schools offered work in home economics, while in two thirds of all the

larger school systems it was a required subject for girls in the seventh and eighth grades. In many cities it was also required in the fifth and sixth grades. In addition there should be noted the work in the continuation and night schools and that offered farm women as a part of the rural extension program of the state colleges and universities.

Before the nineteenth century the home in large part produced what it consumed and consumed what it produced. But with the advent of industrialism its economic function shifted from the making of goods to the rendering of services, and the manufacture of articles for consumption became centered in shops and factories. Until well into the twentieth century, however, even in urban communities cooking, sewing and laundering continued to be done in the home. With the increasing employment of women in stores and factories and their consequent lack of home training in domestic tasks a need arose for more formal instruction in the household arts. This fact coupled with the growing application of chemistry and bacteriology to the problems of nutrition led to development of the early cooking schools and domestic science institutes common in the eastern part of the United States during the 1870's. These schools intended for adults were based on the theory that "young housekeepers in moderate circumstances, young women employed, and the wives and daughters of working men" needed instruction in plain family cooking. Sewing and dressmaking, a heritage from convent training in needlework, were likewise taught. During this same period an awakened social interest in the status of the domestic servant was responsible for the establishment of schools, notably in Boston, for the training of skilled household workers.

The recognition of the necessity for instruction in home making was soon interpreted to mean that it should be given in youth and that the public schools should take over the responsibility. This movement was hastened by the contemporary interest in manual training, an emphasis based on the theory that it was the duty of educators to train the whole child, to encourage him to manipulate materials and to create and to familiarize him with the activities of the world about him. As a consequence during the decade between 1880 and 1890 both manual training and household arts were quite generally introduced into the larger public schools of the United States, first into the high school and later into the elementary grades.

By 1910 the inclusion of industrial and household arts in the school program was being supported by a new argument, the vocational. The National Society for the Promotion of Industrial Education was founded in 1906. Included definitely in its program was the training of girls for home making. In 1917 Congress passed the desired legislation, the Smith-Hughes Act, providing federal aid in the carrying out of state programs for the training of persons over fourteen in agriculture, trade, industry and home economics. The effect of this act was not only to stimulate courses in home economics but also to standardize and improve the quality of the work offered. Only those schools whose teachers, courses and equipment meet the requirements of the federal and state boards for vocational education receive federal funds.

In the case of colleges and universities the introduction and development of home economics as a part of the curriculum were largely western or middle western movements. During the period in which cooking schools were being introduced into the elementary grades of the industrial cities of the east, departments of domestic economy were established in the agricultural colleges of Iowa, Kansas, Illinois and other middle western states. This was a natural outgrowth of the purpose for which these schools were established. Under the Morrill Act of 1862 public lands had been donated to the states to provide colleges for the benefit of agriculture and the mechanic arts. Since coeducation was well established in the middle west, courses for the farmer's daughter as well as the farmer's son were considered necessary. The farm home was an integral part of the farm business as a whole, and courses in home economics were therefore essential to the training which it was desired to give to the people living in the great agricultural states.

This close association between agriculture and home economics in the college has had certain noteworthy results. When it has involved the supervision of teaching and research in home economics by the agricultural director it has meant a sympathetic understanding that might not have been secured under other direction. But it has also meant that the development of home economics was subject to the limitations inherent in this association, which, originally accidental and fortuitous, came to be regarded as necessary and inevitable. Moreover the attention of the home economics staff both in organizing curricula and later in research came to be con-

centrated almost exclusively on the farm or rural home. Since various techniques and skills, such as canning, baking, sewing and laundry work, which urban home makers were abandoning remained important in farm households they remained important in home economics. Since girls from farms and small towns wanted to know the conventional usages of urban society, home economics assumed the responsibility for democratizing the standard of living of the élite. At present even the federal Bureau of Home Economics is in the Department of Agriculture and is correspondingly limited in its work.

Another association that has been powerful in shaping the objectives and the character of home economics is its connection with departments of education, teachers' colleges and normal schools. The introduction of household arts in the public schools meant a demand for teachers; and some of the best known departments of home economics were organized under the aegis of schools of education, as in the case of Teachers College, Columbia University, and of the University of Chicago. Similar courses with a similar purpose developed at the land grant and liberal arts colleges offering work in home economics. Their graduates also desired to teach; and to qualify them to do so became a major objective even of schools not nominally created for that purpose, a development quite unlike any that occurred in the schools of law, engineering and agriculture or in other departments such as those of chemistry, physics, economics or history. Accordingly the staffs of college departments of home economics were constituted largely of women who held degrees from teachers' colleges and schools of education rather than in the humanities or in the physical or social sciences.

It is not to be understood of course that the development of college work in home economics has been motivated only by the desire to prepare the graduates for employment in the secondary schools. A fundamental purpose has been to provide women with the knowledge, appreciation and understanding that would improve their functioning as home makers and indirectly thereby promote the well being of families. In the fulfilment of this aim departments of home economics have sought to embody in their curricula whatever was pertinent in literature and art and in the physical and social sciences.

Another factor that has influenced the character of home economics courses has been the desire to achieve their recognition as legitimately of college grade. This aim has sometimes led to

undue specialization in advanced scientific courses or to the setting up of unnecessary prerequisites for admission, but when intelligently applied it has resulted in a fruitful synthesis of disciplines around vital problems of the home and the family.

The fields of knowledge which home economics has incorporated into its curriculum and which it has itself increasingly enriched are varied. First to be drawn upon, perhaps because they were most easily available, were the contributions of the chemist, the bacteriologist and the physiologist to problems of diet and health. The study of human nutrition early became a distinctive part of home economics. Applications of chemistry to cookery and other household processes and of chemical analysis to textiles and household supplies were made. Women trained in chemistry, biology and bacteriology appeared on the staffs of departments of home economics, bringing with them the spirit and methods of the experimental sciences. Home economics, formerly represented by the manual, the book of recipes, etiquette or household hints, is today an organized field of knowledge devoted primarily to the application of the physical and biological sciences to the problems of the home maker and the home.

In the application of the social sciences to home economics certain recent trends are worthy of notice. In the earlier decades the social sciences had little influence on the development of home economics. Economics itself tended to lay its main emphasis on problems of business organization, when it was not dealing with theory; and those concerned with home economics had not yet turned their attention from individual situations to social problems. But, largely as a result of the increasing attention given by economists to consumption and to the problems of the consumer-buyer, beginning about 1925 the study of the economic problems of the family was introduced into the curriculum of a number of colleges and universities. As a result also of recent sociological and psychological investigations of the family the systematic study of problems of family relationships is becoming more frequent. Overshadowing both of these developments, however, has been that in child care and training, following the progress in the last decade of the scientific study of child physiology and psychology. The subject itself is of such widespread interest and so appropriate to home economics that there seems danger that the study of the child may result in neglect of that of all

other aspects of family life. Other problems with which home economics is increasingly and rightly concerning itself are public health, housing, recreation—both individual and community—and the role of aesthetics in home making.

The future character of home economics as a discipline both within and supplementary to the formal educational system will be determined by the following considerations. Will it concern itself with the problems of urban life as fully as it has with the problems of the farm and village? Will its training in skill, techniques and managerial capacity be responsive to changes in consumption standards, in home activities and in organization of the household? Will it, for example, train for buying as thoroughly as it has trained for making? What will be its attitude in regard to the economic and social position of women? Is the home economics curriculum to be built on the assumption that to women alone belong certain responsibilities and that their interests and activities will center primarily in their own families? Or will this limiting assumption be avoided and the course of study be focused on questions of the family and family welfare which concern men as well as women?

Finally, are vocational or non-vocational objectives to shape its curriculum? In addition to teaching, home economics graduates are today being called upon to fill a variety of positions as institutional managers; as dietitians in hospitals, sanitariums, hotels and restaurants; as directors of factory and school lunch rooms; as visiting housekeepers for social welfare organizations, family agencies and settlements; as household and budget consultants for banks, insurance companies, women's magazines and manufacturing concerns whose product is food or household equipment. Many of the last employ women trained in home economics as an adjunct to their advertising departments. Candy factories and food concerns often maintain research laboratories directed by home economics experts whose duty it is to test the purity of the particular product and to experiment with new foods. The radio with its opportunity for lectures on food and household products has opened still another field to home economics graduates.

The demand for trained workers to fill these and similar positions is of decided strategic value. On the other hand, home economics will to a large degree fail as an education for women if its avowed objective up to the present time—the integration of home and family problems into the larger life of the nation and the world—is

lost sight of or subordinated to the vocational end.

Despite its relatively recent emergence as a formal educational discipline home economics has developed a considerable amount of literature in both textbooks and periodicals in addition to its foundation of empirical knowledge gained in the past and transmitted from generation to generation. Chief among its various organizations is the American Home Economics Association with a membership of more than 10,000, mainly high school and college teachers. This organization was an outgrowth of the Lake Placid conferences which met annually from 1899 to 1908 for the purpose of systematizing the movement. Its official organ is the *Journal of Home Economics*. An International Bureau has been established at Fribourg, Switzerland, to collect literature on the various aspects of home economics and to serve as a clearing house for information.

HOME MISSIONS. *See* MISSIONS.

HOME OWNERSHIP is socially significant for the most part in terms of urban conditions. Where the farmer owns his farm he attaches no more significance to the ownership of his house than to any of his agricultural equipment. Where tenancy prevails, home ownership is as impossible and housing conditions are as bad as in the slum districts of many a city. Yet it is only to the urban dweller that housing presents itself as a separate commodity and a peculiar need; and it

is among urban and suburban dwellers that special attitudes toward home ownership have developed most articulately.

The significance of home ownership has differed somewhat in the United States as compared with Europe. The modern European city, particularly on the continent, has inherited a tradition of crowding from the days when cities were surrounded by walls and the need of protection made for a contraction of the urban area. This resulted in a system of housing in which independent ownership was difficult if not impossible. The multiple dwelling was the commonest form of housing and only the very wealthy or the very important could afford to indulge in the luxury of a private house surrounded by a garden and protected by a wall or fence. The American city, on the other hand, particularly that built after the opening of the nineteenth century, started out with single, privately owned dwellings modeled on the pattern of the farmhouse—a situation favorable to home ownership. The force of this contrast has been lessened with the rapid urbanization of the United States and the growth of a number of large cities where the multiple dwelling must predominate. Nevertheless, attachment to the ideal of home ownership has persisted among many groups in the United States, while it has lost force in the more socialized communities of Europe.

The popularity of home ownership in the United States is due to several factors, not the least of which is the traditional farming attitude that still colors American psychology. Land and home owning, part of the conception of the good life in all pioneer communities, have been fostered from the start by the government land policy. The urge to own one's own home is further reenforced by the notion that family stability and social prestige as well as civic and community responsibility are thereby engendered. Economic considerations, such as financial security and independence, the development of habits of thrift and provision against adversity, are likewise conducive to home ownership, especially among the wage earning class. Finally, there is general agreement that ownership gives greater security to employment of capital in housebuilding and makes for stable conditions. For this reason home ownership has been deliberately promoted not only by real estate companies and building and loan associations, whose primary concern is the resulting financial profit, but by chambers of commerce and business and civic groups with a vested interest in the com-

munity. Employers have urged home ownership among their workers, since men who own their own homes obviously constitute a more stable type of labor and are less likely to engage in strikes. "Own your own home" campaigns have been fostered in many cities and lots have been sold on what appear to be extremely easy terms. Newspapers and magazines have assisted the movement by furnishing plans and offering their readers advice regarding costs of construction and methods of financing. It is chiefly by these promoters that home ownership on the instalment plan has been advocated.

Rising rents and land values, urban congestion and the growth of suburbs, combined to promote home ownership in outlying areas especially among the middle class. Hampered at first by inadequate means of transportation, this suburban trend was greatly stimulated by the coming of the street car, bus and subway as well as by the increased private ownership of automobiles. The pioneers in this extension of the residential section were compelled to build their own homes, since there were no places for rent and few promoters were willing to invest money in residential property which seemed to entail so great a risk. Real estate companies, however, were quick to take advantage of this spontaneous movement, and suburban residence areas were soon opened up commercially. In some cases only the land was sold in the form of individual lots, each purchaser being left free to build his own home subject to certain restrictions as to size and type or cost of dwelling. In other cases the company erected houses which were usually disposed of by amortizing the cost of the building in a series of rent payments.

Despite its sentimental appeal and its artificial stimulation by commercial interests home ownership in the United States has shown a gradual but steady decline for several decades, as indicated by the following figures:

| | PERCENTAGE OF TOTAL HOMES | |
|------|---------------------------|-------|
| | RENTED | OWNED |
| 1890 | 52.2 | 47.8 |
| 1900 | 53.9 | 46.1 |
| 1910 | 54.2 | 45.8 |
| 1920 | 54.4 | 45.6 |

The percentage of owned homes varies from 37.2 in the middle Atlantic states to 56.4 in the west north central and from 30.7 in the state of New York to 65.3 in North Dakota. Among cities with populations over 100,000 Des Moines ranks first with 51.1 percent home owners, while New York City with 12.7 percent ranks lowest.

These are the 1920 figures, since the census statistics for 1930 are not yet available.

There are a number of obvious reasons for this decline in home ownership. Generally speaking, ownership by the occupant goes with individual dwellings, tenancy with multifamily houses. The latter have greatly increased during recent years in suburban as well as metropolitan areas. The popularity of apartment house dwelling is due to the growing preference of women for work outside the home, their demand for labor saving devices, the desire on the part of both men and women for freedom to move from one locality to another and their unwillingness to face certain economic liabilities that go with the ownership of a home.

It is undoubtedly true that under modern economic conditions the ownership of a home may be as much of a hindrance as a help to the wage earner. The gradual bureaucratization of business and industry with the inevitable shifting of a man from one place to another as the central office may see fit creates a presumption in favor of the loosest possible attachment to a given locality and therefore makes renting more expedient than home ownership. The modern worker in either business or industry is a far more mobile person than was his father, and for him to own a home is in a sense to give hostages to fortune and in time of unemployment to be prevented from seeking work in other localities.

Other obstacles arise in connection with land and building costs, exorbitant taxes and the difficulty of financing a home. It is significant that the number of owned homes in the United States encumbered by mortgages or other liens has been steadily increased during recent decades.

| | PERCENTAGE OF OWNED HOMES | |
|------|---------------------------|------------|
| | FREE | ENCUMBERED |
| 1890 | 72 | 28 |
| 1900 | 68.7 | 31.3 |
| 1910 | 67.2 | 32.8 |
| 1920 | 61.7 | 38.3 |

Undoubtedly the decline in home ownership and the accompanying increase in encumbered ownership are due in part to the fact that it has become extremely difficult for a wage earner to own his own home. Under modern conditions it is almost impossible for him to save enough to pay a sufficient instalment on the purchase of a home. According to the Bureau of Labor Statistics the average cost of single family dwellings built in eighty-five large American cities in the year 1929 was \$4902, exclusive of land. Using the convenient rule of thumb which asserts that a family

should not undertake the purchase of a home costing more than twice its annual income, it follows that for the two thirds of the population whose income is \$1200 or less per year home ownership is out of the question. Only for those whose annual income is in excess of \$2000 is the owning of a home which costs from \$4000 to \$5000 feasible, and economists agree that less than one third of the population of the United States falls within this group.

For those in the upper income brackets who are able to furnish in cash 25 to 50 percent of the purchase price it is relatively easy to secure a first mortgage on the remainder through banks, insurance companies, private investors or building and loan associations. The last named, it is estimated, have financed nearly 70 percent of the homes built in the United States since the World War. The popularity of the building and loan associations is due not only to the reasonable terms on which they loan money but to the fact that they are specialists in this type of lending and are able to offer the home builder expert advice which saves him much inconvenience and expense.

The building and loan societies do not, however, meet the problems of families who can supply only 10 to 20 percent of the purchase price of a home in cash and who must resort to a second mortgage or to some kind of instalment purchase arrangement. Second mortgage rates, taking into account commission, discounts and other charges, are frequently so high—20 to 50 percent per annum in some cities—as to stifle home ownership. In order to combat this evil the American Bar Association and the American Mortgage Bankers Association are urging uniform mortgage laws for all states for the purpose of facilitating sound home ownership. The Conference on Home Building and Home Construction called by President Hoover in 1931 proposed as an immediate step the establishment of a system of home mortgage loan discount banks with the twofold purpose of relieving existing financial strain in the provision of small mortgage loans on urban and farm properties used for homes and of supporting various institutions in aiding the revival of home construction and alleviating unemployment.

In Europe the housing shortage after the World War led to extensive participation in housing schemes by most governments. In Germany and Austria municipal building or government aid in the construction of large multiple dwellings predominated. But in a number of

countries, particularly Great Britain and Holland, there have also been developed non-commercial financing schemes under government auspices which have made it possible for an increasing number of families in the middle and lower income groups to own their own homes. In England the Small Dwellings Acquisition Act was designed to promote home ownership among the working classes; and considerable progress has been made, even though a large proportion of the British people are renters by habit and preference.

In the cities of France and Italy the large apartment house is still entrenched and in Belgium the small one. Nevertheless, the Public Housing offices in France are doing a great deal to promote individual home ownership especially in smaller cities and rural districts. The Belgium General Savings Bank lends at a low interest rate for twenty-five years 80 percent of the money needed for purchasing a home. In Sweden under the Own Home law the government in effect offers second mortgage money at 5 percent interest. New Zealand has developed a similar system by means of which families in the middle income group are protected from exploitation and enabled to meet the problem of financing a home.

In the United States the situation has not been so clearly recognized, and efforts to meet it have been confined chiefly to private enterprise. One or two legislative efforts are, however, deserving of mention. Since 1916 the government has through the Federal Farm Loan Act provided the machinery for financing farm homes. Under the terms of this act the Federal Land Banks loan money to farmers for "building and improvements." Since homes are included in this general category, it is difficult to say to what extent the act has definitely fostered home ownership among the rural population.

Similar efforts directed toward the financing of farm homes have been embodied in legislation in Oregon, Oklahoma and South Dakota. In California the Veterans' Farm and Home Purchase Act passed by the legislature in 1921 authorized an issue of bonds to the amount of \$10,000,000 for the purchase of homes and farms to be resold on the instalment plan to veterans of United States wars. In 1925 and 1929 additional bond issues of \$20,000,000 each were approved. The state spends not more than \$5000 for a home or \$7500 for a farm. The home may be one already erected or one which is to be built. The veteran must pay 5 percent of the purchase price

as a down payment or 10 percent of the price of a farm and 5 percent in either case to cover the cost of administration throughout the life of his contract. He amortizes the remainder of the purchase price and pays 5 percent interest on the balance in equal monthly instalments extending over twenty years. According to figures issued by the Veterans' Welfare Board, which administers the Farm and Home Purchase Act, 7213 homes and 290 farms were purchased by veterans during the first decade following the passage of the act. As an aid to home ownership this act has proved highly successful, particularly since it has involved no expense to taxpayers. The California Commission of Immigration and Housing has urged the passage of a home purchase act to apply to all families within the small income group.

It is evident that the whole question of home ownership has become inextricably involved with the income-wage problem. At present the building of single family dwellings on a commercial basis is carried on almost exclusively for the top economic third of the population. Home ownership can be augmented only through increasing incomes in the lower groups or decreasing the costs of building small homes. Even should the construction of small individual homes on a large scale prove economically feasible, it is evident that some degree of coordination of efforts on the part of public agencies as well as some degree of public control will certainly be necessary if home ownership is to provide its share of the adequate housing facilities of a nation.

HOME RULE may be broadly considered as including all forms of local or regional self-determination. Thus in Great Britain home rule for Ireland was long a burning issue (*see* IRISH QUESTION), and the expression "Home rule all around" is still occasionally used to indicate the aspirations of Scotland and Wales for self-determination (*see* DECENTRALIZATION). In the United States the term is most generally applied to an arrangement under which municipalities are permitted to frame their own charters and regulate their local affairs. Such arrangements have sometimes been provided for by statutes passed by the state legislatures, but because statutes have proved inadequate guaranties the term has generally come to be confined to arrangements based on constitutional provisions alone. It is in this sense that the term is here used.

Municipal home rule is a comparatively recent development in the United States, having evolved almost entirely within the last fifty years. Its progress has been due in the main to three causes: the increasing complexity of municipal problems resulting from the rapid growth of cities; the popular belief that problems of municipal government do not receive adequate attention from the state legislatures; and the desire to separate municipal from state politics.

In colonial America a borough or city received its charter from the governor of the colony in which it was situated. The colonial assemblies had no authority either to grant, to amend or to repeal such charters. Nor could the governor use his power to interfere in local affairs, for it was an established principle of English law that the crown could not revoke a borough charter except with the consent of the grantees. The American Revolution, however, changed this situation. The new state legislatures assumed the power to grant city charters and to amend or revoke them at will. At the outset the legislatures did not exercise this authority except on the petition of the cities themselves, but in the course of time they began to intervene on their own initiative. This interference took the form of special legislation which the legislatures enacted for individual cities, more particularly for the largest municipalities. By such special legislation the state authorities determined the form of city government, provided the methods by which city officials should be chosen, allocated their powers and in some cases even fixed their salaries. Similarly they prescribed the system of local taxation and fixed limits to the amount of money which a city might borrow.

Toward the middle of the nineteenth century with the development of public utilities in the larger cities the practise of legislative interference in matters affecting franchises became frequent and ill advised. Special laws granted to private corporations exclusive privileges for supplying cities with water, gas or horse car service. Such measures were usually promoted by interested parties who sought and obtained from the legislature what they could not secure from the municipal authorities. In other words, the state legislature allowed itself to be used as a court of appeal from the decisions of the local governments in matters of purely local concern. Moreover its decision in such matters was often determined by political motives and the best interests of the cities were regularly sacrificed to serve partisan ends. Beginning in the states of the Atlantic seaboard this practise of legislative intermeddling spread into the newer western commonwealths and reached its climax there during the two decades which followed the Civil War.

Various attempts were made to restrict the omniscience of the legislature over municipal affairs. These took the form principally of constitutional prohibitions upon legislative interference in specific local matters and general constitutional prohibitions upon special legislation by the state for particular cities. The failure of these and similar measures to provide adequate relief led to the demand for constitutional provisions establishing the principle of municipal home rule. Missouri in its constitution of 1875 was the first state to recognize this demand by providing that the voters of a city might elect a board of freeholders with power to draft a municipal charter which on being ratified by popular vote would go into effect and be controlling as respects all matters of purely local concern. Four years later California incorporated a somewhat similar provision in its new constitution, and the example was subsequently followed by various other states. Sixteen states now have constitutional provisions insuring some measure of home rule to the cities.

Among these various home rule states there are considerable differences in the scope and nature of such constitutional provisions. Generally speaking, they give the cities power to make and amend their own municipal charters, but with a variety of limitations. One limitation is that the provisions of the city charter shall be consistent with the constitution and the general laws of the state. Another restricts the charter

provisions to matters which are of local importance only. Authority over all questions of more than local concern is reserved to the state legislature. The wording of this limitation differs from state to state: in California the home rule authority of the cities is restricted to control of their own "municipal affairs"; in New York it extends to matters affecting "the property, affairs or government of cities"; in Ohio it includes "all powers of local self-government . . . as are not in conflict with the general laws." Some other state constitutions make a detailed list of the specific matters which shall be deemed to be within the home rule powers of the cities.

The inherent weakness of the home rule charter system lies in the fact that no clear separation can be made between matters which are of strictly local importance and those which directly or indirectly affect interests outside the municipality. Governmental authority is not a thing that can be mapped off into blocks and lots like a tract of land; it is a field that is always expanding or contracting, besides being constantly changed in the urgency of its exercise. Moreover new powers to be exercised by somebody are steadily coming into the field. Hence the line of demarcation between matters of local and general interest is becoming increasingly difficult to draw. For this reason the courts are being called upon to decide large numbers of controversies on this point, and in general their decisions have tended to whittle down the field within which the home rule authority is paramount. Questions which relate to such matters as elections, police, public utilities, taxation, assessments, public health and education have one after another been adjudicated to be of general as distinct from local importance. When the provisions of a home rule charter conflict with state laws, these grants of authority have generally been held invalid.

Another limitation on municipal home rule relates to the procedure by which home rule charters may be framed and adopted. In some states the initial step is taken on the petition of a prescribed number of voters; in others the city council must make the first move; and in one state, Minnesota, the initiative rests with the district judges. In New York the drafting of a new charter may be done by the city council or by a special charter commission. But home rule charters are almost invariably framed by a special body commonly known as the board of freeholders, the members of which are elected by popular vote. The finished document must

then be submitted to the qualified voters of the city for their approval. If the voters approve it by a majority vote the charter goes to some designated public official for filing and thereupon becomes invested with the force of law. In a few states, however, it must go to the governor or to the state legislature for approval before becoming effective. This of course is a mere matter of form inasmuch as neither governors nor legislatures are in the habit of changing any provision in a home rule charter which has been adopted by the voters of the city.

The home rule system has some conspicuous merits. It enables a city to obtain the general type of governmental organization which the people desire. It insures greater care in charter drafting. Home rule charters are on the whole more concise, less ambiguous and more workable in their provisions than are charters which have been framed by legislative committees. There is more originality in home rule charters; those who frame them are more ready to try experiments. The home rule system likewise lessens the burden on the legislatures. With the rapid growth of cities it has become virtually impossible for legislatures in the more populous states to bestow adequate attention upon all the problems of urban government. Furthermore the home rule system releases the cities from bondage to those rural representatives who often form a majority in the state legislature but who have no special knowledge, interest or competence in municipal affairs. Finally it makes possible the divorce of municipal from state politics. So long as the state legislature possesses the right to interfere in city affairs and so long as it adopts the policy of doing so, there is little chance of keeping state and municipal issues apart.

The objections to municipal home rule arise almost wholly from the practical difficulties involved. To the extent that the welfare of the entire state is regarded as more important than the desires of its individual communities there must inevitably be restrictions on municipal self-determination. The city is merely the agent of the state for the performance of such functions as can be more efficiently performed by delegation. It has no inherent right of self-government. The question as to how much authority should be devolved by the state upon its municipalities is one of expediency, and the list of functions which can be profitably administered in this way is steadily diminishing.

From the cities the home rule movement has

extended in a few states to the counties as well. It has resulted in provisions which authorize the adoption of county charters in such states as California and Maryland. It seems open to question, however, whether cities and counties can properly be placed upon the same plane in this matter, for the position of the county as a governmental agent of the state makes it advantageous to have some reasonable degree of uniformity in county administrative methods.

In the countries of Europe neither cities nor counties have any constitutional guaranty of local self-determination. On the other hand, they are in most cases governed under the provisions of general municipal codes which in some of these countries are sufficient to insure a reasonable measure of protection against outside interference in local affairs.

HOMESTEAD. The homestead is a piece of land granted to a settler on condition that he live on it and cultivate it or otherwise utilize it as the basis of his livelihood. The granting of homesteads involves underlying political, economic and social principles. Politically it is a means of providing a population for a vacant territory. Economically the homestead is supposed to eliminate poverty, insure an equitable distribution of wealth and provide a perennial stream of new, original wealth. Socially it is designed to relieve discontent in populous centers and to furnish an opportunity for healthy development of surplus population. It should be noted that the important homestead laws have been put through by well nigh irresistible popular pressure; given a democratic form of government and unsettled land, it follows that the populace will compel the passage of some form of homestead law.

In North America the demand for free land arose in colonial times; all the colonial governments gave away some land. In 1783 the United

States government first came into possession of a public domain, the old Northwest Territory, and during the closing years of the eighteenth century Congress was asked to make the land available to settlers virtually without charge. Although Congress first adopted the plan of selling land by auction to raise revenue, much land, for example millions of acres of military grants, was obtained by settlers without payment. Several states, notably Kentucky and Tennessee, early sold state land at a nominal price. Beginning in 1796 the United States offered land on credit but sold little until 1800. After 1814 more than 1,000,000 acres were sold annually until in 1820 a cash system was introduced at reduced prices. In 1825 Senator Benton of Missouri asked Congress to inquire into the expediency of providing free land for settlers. After a long series of acts of a local or temporary nature there was passed the Preemption Act of 1841 which gave the settler the right to bid first on land he had occupied and to purchase it at a minimum price, usually \$1.25 an acre. Western interests soon began to advocate a reduction of prices, which was opposed in the east by those who looked for revenue from sales. Finally in 1854 the Graduation Act was passed. Although this was a concession to the settler it was an even greater one to the speculator since it provided for the sale of all land which had been on the market for a given time at a price between \$.12½ and \$1.00 per acre.

For several decades Congress rejected bill after bill introduced by Benton to provide for the free distribution of land. The chief opposition came from the slavery element dominant in the south, which saw that distribution of western land to the masses would interfere with the spread of the large plantation and would tend through the migration of urban easterners and immigrants from Europe to create a northwest populous and powerful enough to break the slaveholders' political power. As the issue became more clearly defined on class lines, the Free Soil party in its platforms of 1848 and 1852 came to the support of free lands and the Abolitionists and Greeley's National Reform Association used all their influence in that cause. In 1860 the Republican party declared for homesteads, which were an issue in the Lincoln campaign. Since 1840 the leaders of organized labor had fervently advocated the various homestead bills, looking to free land as a way of escape from shops and mills. But not until after the outbreak of the Civil War, when the Free Soilers were left in

control of all the federal governmental machinery, did they put through this objective as well as others. The Homestead Act, which with modifications has been in effect for nearly seventy years, was passed in 1862 and only a military victory was needed to make it effective.

The act provided that any head of a family over twenty-one years of age, either a citizen or an alien who had declared his intention of becoming a citizen, might take 160 acres (within railroad "limits," 80) and after living upon them for five years and making prescribed improvements receive a government patent. The five-year residence requirement was interpreted to mean not less than six months per year for five years, and even this was subject to considerable reinterpretation by land officials and the homesteader's conscience. The act also provided for a "commutation" of the five-year residence requirements into a cash payment of \$1.25, thus making the homestead provisions identical with the preemption obligations; i.e. residence upon the land for a short period and a payment of the minimum price. In the early years of the operation of the act settlers wanted the land and did not care to buy in larger amounts than the quarter section, 160 acres. Only later, when farms of much larger size were in demand, did commutation become common. In wheat districts such as North Dakota and in forested areas commutation became as general as the regular method of homesteading.

The Homestead Act allowed each settler about the quantity of land that had been found desirable for efficient farming in the humid portion of the middle west. The homestead served well as a family farm throughout a strip of territory some three hundred miles wide just east of the 100th meridian, but on the plains and in the mountain states it was ill adapted to the requirements of either farming or land disposal. It was a pronounced misfit and the basis of much fraud in grazing sections, where a quarter section was worth little, in areas where irrigation was needed and especially in forested areas. Many rather ineffectual efforts were made to mitigate difficulties besetting the great majority of homesteaders to the west of the 100th meridian, whose small capital had soon been exhausted and many of whom had been ruined by drought or grasshoppers. The Desert Land Act of 1877 provided that 640 acres might be granted per person, that the grantee was to irrigate the land, to live upon it at least part of the time and eventually to pay \$1.25 per acre. In 1891 the grant

was reduced to 320 acres, but a man and his wife might each take a grant of that size. After the Desert Land Act proved a failure Congress passed the Carey Act in 1893, the Reclamation Act in 1902 and the Grazing Homestead Act in 1916. The last makes available homesteads of 640 acres, still insufficient for grazing purposes in a country of sparse pasturage.

Another major effort to modify the Homestead Act for the humid section was the Timber Culture Act of 1873 providing for the taking up of a quarter section of land by any settler who would plant forty (soon cut to ten) acres of it to timber. Thus it was hoped to develop shelter belts, increase rainfall, lower summer temperatures and effect other improvements in climate. The act succeeded only in getting rid of some millions of acres of public land.

More than a quarter of a billion acres were given away under the Homestead Act and its amendments, all of which carried out the popular view that the sooner public lands were turned into private property the better. Always keen for development and prompt returns, the west looked on private property as its main stimulus. Speculators and land companies by the purchase of military and other scrip, by bribery and misrepresentation, contrived to obtain vast tracts theoretically destined to small settlers. Subterfuge and fraud were generally winked at or condoned on the strength of the prosperity which the exploitation of natural resources seemed to promise.

All in all the homestead acts served to spread population too rapidly over a wide stretch of territory. Social relationships suffered, education lagged and, most basically, the prices of farm products collapsed. Land was being used too soon and in too great quantities in relation to other occupations and developments. The economic machine was thrown out of balance. There is good evidence that the movement of dissatisfied eastern laborers to western lands was small. On the other hand, the homestead laws prevented undue increase in the proportion of people dependent on wages by draining off potential oversupplies of labor to the prairies; but this process created an overabundance of farmers, who were in turn to flood the labor market. Thus the effect of the homestead system on the labor movement was mainly one of delaying developments. As long as western lands absorbed most of the population increase, labor had the advantage of lessened competition and of cheap food furnished by the farmers of cheap land.

But after the hope of easy escape to western lands was closed about 1890, the American labor problem took on a sharper form and the labor movement began to develop its greatest strength.

Canada is the only other country in which the free homestead has enjoyed the importance that it has had in the United States. The Canadian system has not differed greatly in form or influence from the American and like its prototype has permitted the exploitation of new land at the settler's will. There has been a certain amount of mutual influence both in legislation and in the effects of the laws. The region of the Prairie Provinces was long an object of Canadian national aspiration; its settlement and acquisition by the Americans were particularly feared and in order to develop it rapidly the recently created dominion government enacted a homestead law in 1872. The size of the homestead was fixed at 160 acres. From 1879 to 1889 preemption of a second quarter at \$1.00 an acre was allowed. The grant of alternate sections within the railway zone to the company served together with preemption to scatter the population, with consequent burdens upon local government. Provision was made, however, for settlement in villages. As a result of the large number of land companies arranging loans to help settlers clear their homesteads such loan schemes were subjected to the sanction of the government in 1886, but the law was far more advantageous to the companies than to the settlers or the government. Not until the completion of the transcontinental railway, a rise in agricultural prices, the improvement of the milling process, the end of homesteading in the United States and the inauguration of a vigorous immigration policy did the homestead succeed in settling the Canadian west. A great boom characterized the period from 1900 to 1913. Speculation was rampant; much submarginal land was taken up, later to be abandoned. Overbuilding of railways eventually resulted in a gigantic burden on the dominion government. An important contribution to homesteading success was provided by American farmers who, having sold their improved homesteads in the United States, thus came to Canada with both capital and experience. The result in the United States of this exodus was the reduction in 1912, with a slight variation in detail, of the required period of residence on the homestead to the three years required in Canada.

As the quarter section was held to be too small for grain growing regions, preemption of

a second quarter at \$3.00 an acre was again allowed in 1908. Although two quarters did not satisfy the demand of many farmers, it was not difficult to bring several homesteads together in larger holdings. Much land went into cultivation during the World War, and as high prices were anticipated in 1918 preemption was abolished. With the accessible lands taken up, the opening of land requiring more railway building was discouraged and the homestead lands played a smaller part than repurchased lands in the soldiers' settlement project of the government. In 1928, however, the number of homestead entries began to increase considerably; but in 1930 the bulk of the public lands was turned over to the provinces in which they were situated in order to place the Prairie Provinces on a par with the older ones, which had retained their lands, and to give them the benefit of the revenue to be derived. In the adjustments it appears that some consideration will be given to the revenue lost to the provinces despite the fact that the lands were given away in free homesteads. At present the provinces which provide free homesteads are British Columbia, Ontario and New Brunswick; in the last two only remote or inferior lands are offered gratis. It appears therefore that the scope of the homestead in Canada will be considerably restricted in the future.

In Australia, after a period during which settlers were allowed to take substantially as much land as they could pretend to use subject to a quit rent, which went uncollected, the disposition of public lands was dominated by the misinterpreted theories of Edwin Gibbon Wakefield. Wakefield considered the backwardness of the British colonies to be the result of a maladjustment of the factors of production and advocated the establishment of a price for land sufficient to prevent its too rapid acquisition by laborers needed to bring capital into play and sufficient to insure the scientific diffusion of settlement and to facilitate by the resulting revenue the introduction of a proper type of colonist. The result of the theory, on the whole, was stagnation. This period from 1831 to 1861 witnessed the ascendancy of the sheep owners, favored by the demand for wool and the semi-arid environment. As squatters on the public domain they entrenched themselves with fixity of tenure on leasehold and with preemptive rights in 1847. The gold rush of 1851 brought a population which eventually turned to agriculture and engaged in a struggle with the squatter. Settlers from the United States brought American ideas

of land disposal. Their influence is to be seen in the adoption by the various colonies of acts providing for the "free selection" of limited amounts of land before or after survey and its purchase by instalments with residence and improvement conditions. The most radical of these laws was enacted in 1861 in New South Wales. Without segregation of pastoral and agricultural lands and without proper administration the result was blackmailing by selectors and dummying by the squatters, who emerged victorious, their leases converted into freeholds. Safeguards were developed in other colonies, but the increase in cultivation did not meet expectations. Within the last fifty years scientific advances have increased the possibilities of agriculture; legislation on behalf of small holdings has modified the principle of free selection by classification of land as well as by leasehold tenure, and with better administration it has been more successful. The free homestead grant was adopted in Western Australia in 1893 and Queensland in 1908. In the latter the Labour party ended all alienation in freehold beginning with 1917. The Western Australian homestead consists of 160 acres but the selector in wheat areas is expected to take up at least 1000 acres, the holding outside the homestead being acquired by "conditional purchase," usually on instalments. The era since the introduction of homestead legislation in the state has been characterized by a vigorous governmental campaign to absorb into agriculture the miners brought by the gold rush in the late eighteen eighties and early nineties. An agricultural bank established in 1894, railways, a water supply first developed for the mines and the easy terms for land acquisition brought prosperity to a state in which the potentialities of wheat are good. These factors also inspired an attack upon the wet, heavily timbered southwest, where fruit growing and dairying are considered more suitable and where the heavy cost of clearing often limits the holding to the free homestead grant. In 1921 there was adopted a group settlement scheme according to which the settlers should work together for wages to clear their lands, but it has been an expensive experiment which has had to be considerably modified.

After many years of a haphazard Algerian colonization policy a form of homestead policy was adopted by the French government in 1878. In an effort to settle French peasants and make the colony a wholly French country free grants were offered. A system of officially founded villages was combined with this homestead regime

in an effort to prevent frauds and displacement of the small settler. Three years' residence and the creation of improvements to the value of 100 francs per hectare were the conditions of the grants. From 1881 to 1891 population increased considerably under the homestead policy. Shortage of public lands and other difficulties led to the theoretical abandonment of the homestead policy in 1904, but even thereafter "exceptional" grants were more numerous by far than outright sales. General economic conditions unfavorable to colonization continued, however, to prevail during the period of grants as before.

Although American legislation has had its influence upon the confused and poorly administered public land laws in Latin America, the homestead in North American form has prevailed only to a slight extent. Where it has been adopted it has frequently been applied only to inferior and remote lands and has come too late to change the general agrarian situation. Because of the failure to attract a large immigration such as that into the United States the tendency was to make grants to concessionaires, who were to colonize the land with foreigners, rather than to individuals for their personal settlement. Moreover the influence of political jobbery and of the financial duress of governments has often been more decisive than the desire to foster genuine land settlement.

In 1863 the Juárez government in Mexico enacted a law, modeled somewhat upon the American legislation of 1862, permitting at a price the denunciation of as much as 2500 hectares of the public domain. With other measures it created a class of small proprietors totaling about 50,000 in 1910, but in the Díaz era the laws were modified so as to enable the alienation of enormous tracts to corporations. To increase the number of individual holdings as opposed to the communal tenure involved in the other agrarian reforms of the period the free homestead was established in 1923. Areas denunciable varied according to the type of land with 500 hectares as the limit. After a considerable area had been alienated the law was suspended upon the enactment of a colonization law in 1926. Following an economic crisis the national government in Argentina enacted public lands and immigration legislation in 1876. Among the provisions was the free grant of small areas to the first hundred families in a settlement. What has been called a grotesque parody of American legislation is a homestead law enacted in 1884 for pastoral lands in frontier territories. Grants were

limited to 625 hectares. In this period public land administration was in the hands of unsympathetic and unscrupulous officials; land nearer the population centers could be obtained in larger tracts with less effort and a spirit of land speculation was dominant. Only after the final crash of the land boom in 1891 were a limited number of colonies founded under the homestead law. In 1903 a new system was inaugurated and again sections of agricultural and pastoral lands were offered free to the early arrivals, but the terms were hard and the territories distant. In 1917 a homestead law was enacted for certain remote regions, and sections of 20 to 200 hectares were granted. Paraguay enacted a similar law in 1918, with grants consisting of 10 or 20 hectares according to the section of the country. In Colombia it has been possible for a good many years to acquire a certain amount of public land by cultivating and residing upon it or by introducing stock and improvements.

Chile witnessed a long struggle between those who sought land privileges for nationals and a ruling oligarchy interested in land speculation and concessions and profiting from legislation providing a certain amount of land for the head of each immigrant family settled, with additional amounts for children. As early as 1896 land was provided for emigrants to Argentina, while a law for national colonization conceding grants less extensive than those for foreign colonization but with the same kinds of assistance was enacted in 1898. By a regulation of 1902 the officials succeeded in making the terms harder and the grants even smaller and refused to concede the assistance granted to foreigners. Recent legislation has taken a more patriotic point of view. A lesser portion of a scheme for land colonization under legislation of 1928 provides for the grant of fair sized lots of public land in certain regions to individuals who are worth 10 percent of the value of the land.

At present there appears to be no great enthusiasm for the homestead system in Latin America. It is argued that it is more important to break up the uneconomic system of extensive cultivation on the large estates than to spread out a still rather small population into the inaccessible regions where public lands, often of inferior quality, exist and where the assimilation of an immigrant is difficult; that the enormous immigration as well as the domestic population which made possible rapid development sufficient to compensate the loss of the proceeds of land sales in the United States is lacking and

cannot be expected; that much land is unsuited to the small holding; and that the free denunciation of land affords no guaranty of its acquisition by a competent agriculturist, a possibility that ought not to be risked, as the extension of credit and other facilities is often necessary. For the ignorant Indian the procedure of homestead survey and entry is considered too complicated and the system of ownership involved is held to be alien to his concepts of tenure. Colonization by the state or by private enterprise with more or less state supervision seems to be favored, a method which more than homesteading is in accordance with traditional procedures as well as with a certain amount of contemporary thought regarding land settlement.

HOMESTEAD EXEMPTION LAWS are legislative devices of purely American invention intended primarily to preserve the integrity of the family as the basic element of societal organization and incidentally to encourage colonization by exempting the family abode, within designated limits of space and value, from forced sale in satisfaction of the homesteader's debts. These laws are frequently said to be derived from the feudal land law of England, which permitted the alienation of lands to be greatly restrained by the use of entails and strict settlements and by provisions for the widow's dower and thereby tended to preserve homesteads and family lands to the family succession. But these rules of the common law, serving political and economic ends, are wholly different from the American homestead exemption laws, which are designed to further sociological and humanitarian purposes. There is no evidence that the feudal land law had anything to do with the homestead enactments; the alleged connection is an afterthought of the American courts seeking to find a basis for rationalizing their conclusion that the homestead laws should be liberally rather than strictly construed.

Homestead exemption laws have sometimes been contrasted with personal exemption laws of earlier American origin. It has been said that the latter are for the protection of the individual while the former are intended to secure the family. But an inspection of the lists of usually exempted chattels, which include such items as the family clothing, the minimum of furniture for the family abode, the implements of the breadwinner and often a year's provisions for the family, clearly indicates that the primary function of these laws too is the preservation of the

family. While chattel exemptions find their prototypes in common law rules prohibiting the landlord from distraining certain of the tenant's chattels necessary to his economic existence, they find their origin in the hard conditions of American pioneer life. Primitive law was merciless to the debtor, his default being regarded as in the nature of a crime. Not only all his goods but his body as well might be seized in satisfaction of his unpaid debt. The English law which the American states inherited was hardly less strict.

When English settlers in the New World found themselves committed to a grim struggle with the great wilderness, it is not surprising that they came to an acute realization of the value of each pioneer's family to the community, the great hazards of uncontrollable circumstance to which that family was exposed and the desirability of affording it every reasonable protection. There naturally developed a frontier philosophy that would throw a portion of the risks of the struggle upon the creditor, and the chattel exemption laws were devised to save the family from destruction by legal process.

The extension of these statutes to preserve not only the family furniture but the family abode as well was a natural step but a very long one, offsetting many deep seated common law prejudices. It was not until January 26, 1839, that the legislature of the Republic of Texas, newly freed from the political control of Mexico and also from some of the inhibitions of the common law, enacted the first homestead exemption law. This act, which served to fix the pattern of legislation in many other American states, provided that there should be reserved to every head of a family in the republic, free from legal execution, "fifty acres of land or one town lot, including his or her homestead, and improvements, not exceeding five hundred dollars in value." The homestead exemption idea proved so generally acceptable that it was carried into the constitution of 1845, adopted shortly after the admission of Texas into the American union, and into the later constitution of 1876; in each instance the extent of the allowable exemption was enlarged.

The movement for homestead exemption laws made rapid progress. Provisions for homestead exemptions in varying forms were made in 1841 in Georgia and Mississippi; in 1849 in California, Iowa, Vermont and Wisconsin; and in 1850 in New York and Ohio. Homestead exemption laws are now in force throughout the United States except in Delaware, Indiana, Maryland, Penn-

sylvania and Rhode Island and the District of Columbia.

Twenty-five states have incorporated some provision for homestead exemption in their constitutions. In nine states, California, Colorado, Illinois, Montana, Nevada, North Dakota, South Dakota, Washington and Wyoming, the constitutions merely enjoin the enactment of proper legislation without specifying the extent or character of the homesteads to be exempted. In Mississippi the constitution contains the mere statement that the legislature shall not be prevented from regulating the sale of homesteads. In Georgia the homesteader may claim a "long" constitutional homestead or a statutory "short" homestead but not both. In three states, Alabama, Tennessee and Utah, the minimum valuations fixed by constitutional provisions have been enlarged by legislative enactment. In the twelve remaining states, Arkansas, Florida, Georgia, Kansas, Louisiana, Michigan, North Carolina, Oklahoma, South Carolina, Texas, Virginia and West Virginia, the statutes have adopted the limitations specified in the constitutions.

The homestead laws of the several states exhibit a common purpose but they vary greatly in detail and scope. The limitations set upon the value of the exempt homestead range from \$500 to \$8000, and those upon the extent of rural property from 40 to 320 acres with 160 acres as the most common exemption. Only a minority of states have taken the Texas legislation as a model, for in most states no distinction is made as to the rural or urban location of the homestead; merely a limitation of value is provided, which most commonly is \$1000. There has been a considerable amount of new homestead legislation since the World War. At least six states, Montana, North Dakota, Oregon, Utah, Vermont and Wyoming, have amended their homestead acts, in every instance enlarging the extent of the existing exemption.

In a few states the homestead exemption exists in favor of any person. The Vermont statute uses the expression "natural" person and the Wisconsin statute speaks of a "resident." In California and Idaho a homestead of lower value may be claimed by others than heads of families. But ordinarily the statutes give the privilege of declaring a homestead to "the head of a family" or to a "householder." "Family" is construed to mean not merely minor children living with their parents, but any group of persons nearly related who live together as a social unit dependent upon a common "head." On the death of the

original homesteader the privileges of the homestead pass with the inheritance to the survivors of the family group and continue for their benefit until the youngest child reaches his majority or until the last dependent dies.

In some states careful provision is made for the notification of subsequent creditors by requiring some form of declaration of homestead to be registered, but in most a looser procedure permits the debtor without previous declaration to set up his claim of homestead to defeat a creditor's levy of execution. In nearly all states the homesteader's power of alienation is restricted to some extent, but there is much variation in the degree of restraint imposed. The usual provision is that the homesteader if married can alien the land only if joined by his spouse.

Certain liabilities are usually expressly excepted from the claim of homestead exemption. It does not thus ordinarily extend to preexisting liens, to governmental liens for taxes or penalties or liens for material and labor expended in improving the homestead. Whether the exemption extends to claims for torts or fiduciary defaults depends upon the wording of the statutes. Purchase money mortgages are practically everywhere excepted, even in such states as Texas and Georgia where the policy of the law has been very restrictive and no subsequent mortgages are valid. In most states, however, incumbrances may be freely created provided the husband and wife consent.

The American homestead exemption policy has been accepted in many parts of the world. Laws of the American type have been enacted in the American possessions. The exemption in Alaska is 160 rural acres or one quarter of an urban acre but may in neither case exceed \$2500 in value; in Hawaii, one acre with the dwelling and buildings thereon, but the property may not exceed \$1000 in value; in the Philippine Islands a limit of value is fixed at 150 pesos, and in Porto Rico at \$500. The movement has also spread to the western provinces of Canada, in which social and economic conditions are similar to those obtaining in the western part of the United States and which were partially settled by persons from the latter area carrying with them the social philosophy of the American frontier. Thus in Alberta, British Columbia, Manitoba and Saskatchewan homestead exemption laws of the American type are in force with limitations of value ranging from \$1500 to \$3000. In all but British Columbia, where no distinction is made

between rural and urban homesteads, the rural acreage within the limits of value may be 160. The policy of homestead exemption has also been accepted in other countries where pioneer conditions have obtained. Such is the case in Brazil and Venezuela, but the laws place no fixed limits of value upon the homestead. South Australia and New Zealand passed homestead acts in 1895, which are constructed according to the American pattern; the limits of value are £1500 and £1000 respectively.

An altogether different type of homestead exemption, which likewise originated in the United States, has also been adopted in other countries. The Federal Homestead Act of 1862 contained exemption provisions protecting the grantees of the public land. Acts similar to this, except for the fact that the exemption granted to settlers on public lands sometimes extends a limited time only, have been passed in Canada in the provinces of Ontario and Quebec, in Newfoundland and in Australia in the states of New South Wales, Queensland and Western Australia. Such laws function primarily to attract settlers upon public lands.

In Europe beginning with the last quarter of the nineteenth century the depressed state of agriculture and the prevailing economic distress of the small cultivators of the soil induced a marked interest in the American homestead policy as an incident of the general humanitarian movement of the period. Laws of the American type have been adopted since the beginning of the present century, but European commentators in tracing the history of the homestead movement on the continent have included many types of laws whose inspiration was certainly quite different from that of the American. Thus the earlier laws in eastern Europe, particularly in the Balkans, were part of an agrarian policy which sought to prevent the partition of the holdings of the small peasant proprietors. Other early laws, for instance, those of Belgium and France, were connected with housing programs.

The first homestead act of the American type was embodied in the Swiss civil code of 1907 (arts. 349-59), which, however, did not go into effect until 1912. These articles empowered the cantons to create agricultural, industrial or residential homesteads and laid down fundamental regulations. The size of the homestead depends upon the needs of the family. The rights of existing creditors must be safeguarded in its creation. To be valued it must be registered in the public land office; and thereafter the owner can neither

mortgage nor sell nor lease it, but during his lifetime he may apply for its dissolution. The French homestead law of July 12, 1909, is very similar, except that a limit of value of 8000 francs is fixed. In Germany on May 10, 1920, after a long period of agitation a federal homestead law was passed allowing not only the state but municipal and other authorities to create homesteads. The law directs that discharged soldiers and the families of deceased soldiers be preferred. The homestead may consist of an urban dwelling or an agricultural holding, which is limited to the amount of land which can be cultivated by the family. Such homesteads are made free from seizure by creditors. A strong motive in all the European homestead legislation has been to prevent flight from the land. In most countries other than the United States the prevailing tendency has been to require the homestead to be specially designated or registered. The owner's powers of alienation have also been much more strictly curtailed.

An Egyptian law of 1912 declared that the property of a farmer owning not more than five feddans of land should be free from forced sale. The exemption extends to the land, the habitation thereon and the beast and implements needed to till it. The purpose of the act appears to be agrarian rather than humanitarian.

HOMEWORK, INDUSTRIAL. The term industrial homework is applied to work carried on in the worker's home for an intermediary who takes care of the sale of the product. The combination of production and consumption activities in the home has been characteristic of agriculture throughout its entire history; even in industry work in the home is much older than indus-

trial homework. The village smithy is adjacent to the blacksmith's living quarters, and the shop of the typical handicraftsman of the guild era was not generally separate from his home. Yet unlike the guild handicraftsman the industrial homemaker does not sell his product directly to the ultimate consumer but is dependent upon a middleman for the disposal of his output. It is this combination of centralization in marketing with decentralization in production that is the distinguishing characteristic of industrial homework. It is a capitalistic form of production, its earliest instances being found in northern Italy in the thirteenth century. As a typical form of industrial organization, known also as the domestic system (*Verlagssystem*), it antedates the factory system (see PUTTING OUT SYSTEM) and persists today in a number of industries and countries. Its history, in the course of which it has assumed many indifferent forms in different periods, countries and industries, may be generalized into a scheme of stages which exemplify the logic of the development but not necessarily its actual sequence for all historical instances.

Industrial homework evolved out of the subordination of the mediaeval handicraftsman to an entrepreneur who possessed a superior knowledge of conditions outside the local market. The new entrepreneur not only interposed himself between the formerly independent handicraft shops and the market but also drew upon the peasant families in the villages, who thus for the first time undertook industrial work for sale. In the second stage of the development an intermediary, the so-called contractor (*Ferger, facteur, commis de la ronde, fattorino, factor*), negotiates between the entrepreneur and the homemaker. He takes care of the distribution of work, gives orders to the individual families and assumes responsibility for the punctual delivery of the product to the entrepreneur. In the third stage the contractor becomes independent of the entrepreneur, who is thereby transformed into a wholesale merchant exercising only indirect influence on production; the relations between them assume the form of purchase and sale and the contractor bears the entire risk of the production carried on by the industrial homeworkers. In the fourth stage the homemaker himself develops into an entrepreneur. He employs in his home hired workers in addition to the members of his family, and homework merges into shop work, often of the sweatshop variety. The entire organization is then built up of the merchant, the contractor, the entrepre-

neurial homemaker, the homeworkers who are members of the family and the hired homeworkers.

Homework means decentralized production, carried on in innumerable small shops with a much more primitive machine equipment than is to be found in large scale industrial establishments. Its persistence in certain trades may be due to the relative backwardness of technical processes, as is the case in the artificial flower industry, toy making, the finishing of garments and in certain types of food handling. Even where the machine process has been adopted for mass production, costly handicraft articles manufactured at home may cater to a special market. In other instances little capital is required to carry on an enterprise and the work can be easily subdivided, as in the case of the garment industry. Finally, the trade may be a seasonal one and the employer may find it more profitable to run his factory on its minimum load, sending out work to homes during the busy seasons. As these factors have ceased to operate, homework has died out; thus the manufacture of cigars by machinery checked homework in that trade and the invention of elaborate knitting machines has greatly reduced the home production of knit goods.

In trades where technological factors do not inhibit the persistence of homework it enjoys from the point of view of the entrepreneur certain advantages in comparison with factory labor. By relegating most of the labor processes to the homes of the workers the employer is able to economize on certain fixed charges, such as rent or interest and amortization charges on his capital, the cost of heating, lighting and maintaining the sanitary standards demanded by law and the various other costs incidental to centralized supervision and control over labor performance. It may be argued that the wage of the homeworker must include an allowance for the expense which is thus shifted to him by the employer. But as a rule the wages paid to homeworkers are lower than those of factory labor which turns out a similar product. Children, semi-invalids and aged persons are more conveniently employed at home than in a factory; similarly the percentage of women is higher among the homeworkers than among the factory workers. Homeworkers cannot be easily reached by organized effort to better their wages; thus they do not benefit by the gains which trade union organization has secured for the factory worker. The influence of trade unions has been

slight except in Soviet Russia, in the cigar trade in Germany and to a small extent in the clothing industry of France. Moreover until the last few decades homework has been free of any of the restraints and costs imposed by social legislation concerning sanitary conditions and accident prevention, and even now it has not been sufficiently affected by such legislation to wipe out the differential of social costs arising from such methods of production.

Homework frequently takes the form of the sweatshop with low wages, long hours and poor working conditions. In new countries with a large supply of immigrant labor the homeworkers are composed in part of foreign handicraftsmen competing with the machine economy. Many types of homework, however, are also carried on by native workers competing with or supplementing machine processes. There is no reason to suppose that the difference between the cost of factory labor and that of homework is not borne ultimately by society in the physical and moral deterioration of the sweated workers; but homework is often profitable to the individual entrepreneur under a system of unregulated labor bargaining.

Statistics concerning the extent of homework are extremely unsatisfactory. In the case of many highly industrialized countries with hundreds of thousands of homeworkers none exist; and for other countries the figures are so meager as to be meaningless. The difficulties of obtaining complete statistics arise from the irregular nature of much homework and from the fact that it is frequently called into being in order to avoid factory regulations and wage and hour legislation and hence exists more or less surreptitiously. Even with a careful investigation of homes the true total cannot be fixed, since, for example, it is easy to deny that a child works at home.

In the United States statistics are available for only a few states and except for New York are of little value. An investigation made for the Association of Governmental Labor Officials in 1926-27 in forty-five states disclosed that homework was widespread in all except agricultural and mining areas; but no detailed description of the extent, conditions or types of homework could be given. In New York state in the year ending June, 1927, 21,573 registered homeworkers were reported, of whom 11,516 were in New York City. This shows an increase over 1913, when 12,221 persons were reported employed at homework in New York state; but this increase may be due simply to improved regis-

tration. The total number of homeworkers in licensed houses in New York state amounts to perhaps twice this figure, and if non-licensed houses are included the number may vary between 60,000 and 100,000. Most of these homeworkers are engaged in the needle trades; over 13,000 of the 21,573 homeworkers were found to be employed in the clothing industry and about 4000 in the embroidery and artificial flower industries. In New York City 33.5 percent of the registered homeworkers were employed on men's clothing, 22.4 percent on embroidery and 15.9 percent on trimmings and flowers. In reality the proportion of workers in these trades to the total number of homeworkers is undoubtedly much smaller, since in non-licensed houses many workers are engaged on other articles the production of which at home is prohibited. The finishing or making of clothes in the home prevails also in California, Illinois, Louisiana (particularly New Orleans), Maryland, Massachusetts, New Jersey, Pennsylvania and Wisconsin. But homework extends to many other trades in the United States. In California and Illinois homework on lamp shades was reported; in Illinois, Connecticut and Pennsylvania the carding of pins and buttons, the making of children's garments, toys and paper boxes and in the latter two states the stripping of tobacco are important forms of homework. The preparation of food and the manufacture of jewelry, brushes and infants' wear at home were noted in Maine, Massachusetts, Illinois and Pennsylvania. Rhode Island reported much homework, especially by children; hosiery and clothing are made at home in Tennessee; the stringing and tagging of bags occupy the homeworkers of North Carolina; in Missouri homework takes a variety of forms, including the manufacture of millinery, neckwear, shoe ornaments, aprons and house dresses. Relatively few of the workers do machine operating; they "finish" garments by hand or perform the more simple operations in connection with production, often taking home at night some extra work after being employed in the factory all day. Homework is not restricted to large cities. In the rural districts of Pennsylvania the farmers' wives work on clothing, textiles and tobacco, which are delivered to them in vans by manufacturers who seek a cheap and unorganized labor in the countryside; and for the same reason homework accompanied by sweating is often found in small industrialized towns and in the areas surrounding industrialized centers.

No general figures are available for the number of homeworkers in Great Britain for the last twenty years; it probably reaches half a million or more. Again, the great majority are employed in the clothing and textile industries. Certain skilled trades are still practised at home and are well paid but most irregular.

In Germany according to official statistics the number of homeworkers was 476,080 in 1882, 457,984 in 1895, 405,262 in 1907 and 405,765 in 1925. In recent years the true number of homeworkers has probably been 800,000 or more. Almost 50 percent are employed in the clothing industry and allied trades and about 28 percent in the textile industry. Woodworking, food industries and metal working are next in showing large numbers of homeworkers. In the Black Forest region chain for mesh bags is manufactured by the rural population and wooden toys, dolls and bead crocheting are produced by cottagers in the mountain districts who own small plots of land but cannot live by their produce. The extent of homework among the farming groups fluctuates with the condition of agriculture and is almost impossible to measure.

In France according to the 1921 census the number of small entrepreneurs and homeworkers totals about 2,300,000. Among them the homeworkers are estimated at 522,000 (157,000 males and 365,000 females). The great majority of the industrial homeworkers are to be found in the textile and needle trades. The manufacture of shoes at home is almost entirely the occupation of men; it is still widespread in the regions around cities. Artificial flowers, often genuinely artistic products, are manufactured by homeworkers in Paris, Rouen and other cities; while laces, feathers, religious articles, jewelry, umbrellas, tapestry and wooden objects are made at home in many sections of France. Changes in fashion and the extension of the homework act of 1915 to these trades, however, have to some extent checked home manufacture.

In other countries statistics of homework are scanty and unreliable. Italy reported about 35,000 homeworkers in 1927 and in Yugoslavia 5 percent of the national income is credited to homework. In Switzerland 35,000 homeworkers were reported in 1929, representing a decrease of more than 70 percent since 1900. The sharp decline is attributed to general popular agitation and to the tendency since 1920 to confine the watchmaking trade to factories.

In pre-war Russia industrial homework was represented principally in the *kustar* industries

carried on by the peasants. Early village handicrafts, which aimed at first to eliminate the dependence of the peasant on the distant town market and to supplement the income derived from agriculture, developed in the course of time into specialized industries with a large output. Growing pauperization made peasant households increasingly dependent upon the income derived from handicrafts, and the lack of capital forced a considerable proportion of such peasant households to undertake piecework for a capitalist employer or to depend upon credit furnished by the merchant who took over their output. Peasants working on a wage basis and those selling their output more or less regularly to the same merchant formed by far the larger part of the *kustar* producers, whose number was estimated at from 10,000,000 to 12,000,000. Of these industries the most important were those based on wood as raw material—the manufacture of furniture, wagons and accessories, wooden parts of agricultural implements, wooden dishes and spoons, window frames and sashes, toys, mats and bast shoes. Certain branches of the textile industry were to a considerable extent in the hands of *kustars*, such as the manufacture of linen, hemp cloth and sacks, rope, unfinished woolen cloth, felt, felt boots and carpets. Rural homeworkers were also important in the production of tanned sheepskin and sheepskin coats, tanned leather, bricks and earthenware and the like. Generally speaking, the *kustars* utilized raw materials readily available in the surrounding countryside and manufactured articles intended primarily for peasant consumption. Nevertheless, some of these industries were concentrated in definite localities and produced for a national market rather than for local consumers. The *kustar* industries are still important in present day Russia; according to the 1925 census there were over 2,000,000 *kustars* in the Soviet Union, a figure which must be regarded as an underestimate. It is doubtful, however, whether they can still be regarded as industrial homeworkers, since the government policy of substituting producers' cooperation for capitalist employment among the *kustars* has been largely effective. On the whole, government agencies and cooperative bodies have taken over the functions of the capitalist employer and merchant in providing credit and raw material and in marketing the finished product.

Statistics show that the total number of homeworkers throughout the world has decreased within the last decades. The laws regulating

homework have multiplied, and it is quite possible that the increase of homeworkers illegally employed has more than offset the decline in the recorded number. Nothing definite is known as to the proportion of male and female and child workers. Owing to the nature of most homework women have always been the most numerous, and no doubt the proportion of women and children so employed has increased with the use in the factories of machinery at which as a rule only men work. The clothing and textile trades still employ the majority of homeworkers; but since women are invading other trades, such as the metal industries, in increasing numbers, the proportion of homeworkers in these industries has probably increased.

Social legislation for the protection of the homeworker is a very recent development. Although legislation was enacted in England for the benefit of the factory workers in the first half of the nineteenth century, the principle of *laissez faire* governed the attitude toward the "small master" and home industry until the last decade of the century. Producers' cooperation, proposed by the Christian Socialists, was directed as much against sweating in factories as in small workshops and the home. Public health acts remained the only resource for those interested in the protection of the homeworker. In other countries a few laws growing out of current ideas about sanitary and wage protection were enacted in the last quarter of the nineteenth century, but with few results. The United States was the first to extend state control over the problems of hygiene in industry in a way that offered a certain degree of protection to homeworkers. The New York law of 1884 prohibiting the manufacture of cigars and cigarettes in tenement houses in large cities was declared unconstitutional, and in 1892 the system of licensing apartments in tenement houses was substituted. The latter although modified several times is the chief measure for the protection of homeworkers today. Massachusetts followed suit in 1891 with a law resembling the earlier New York law, although it could not be enforced for lack of inspectors; and similar laws passed by other states during the same years remained ineffective for the same reason. The report of the House of Lords on sweating in England in the period from 1888 to 1890 dealt particularly with homework, which by this time provided the greatest excesses of unfavorable conditions; and in 1891 a consolidating act took cognizance of the situation by requiring lists of outworkers to be kept by employers in certain

trades and by setting up sanitary regulations similar to those in the United States. One of the chief objects of minimum wage legislation was the elimination of sweating. Protection of homeworkers' wages was first introduced by New Zealand in 1894 and by Victoria, Australia, in 1896; but the laws remained ineffective until the twentieth century, when minimum wage regulation became better organized. During the following years social legislation spread to many countries and states without, however, attaining much practical significance. Really comprehensive and partially effective laws date only from the second decade of the twentieth century. This new epoch was inaugurated by the English Homework Orders in 1911, 1912 and 1913, which extended the 1901 regulations to new trades, and the Trade Board acts of 1909 and 1918, which protected the factory as well as the homeworker; by the German homework law of 1911, amended in 1923; by the law passed in New York state in 1913 entirely prohibiting the home production of foodstuffs, children's wearing apparel and certain other products; by the Swiss minimum wage law of 1917; and by the laws regulating homework and wages in Norway and Austria in 1918 and in Czechoslovakia in 1919. The French minimum wage act of 1915 to prevent outworkers from being paid lower wages than factory hands applied only to women homeworkers in the clothing industry but in 1922 and 1926 was extended to cover all wearing apparel, artificial flowers and feathers, jewelry, laces and the like. By 1920 most of the larger industrial countries had created some sort of partially effective legislation for homeworkers.

In the United States at the present time fifteen states—California, Connecticut, Illinois, Indiana, Maryland, Massachusetts, Michigan, Missouri, New Jersey, New York, Ohio, Pennsylvania, Tennessee, Washington and Wisconsin—have some kind of law concerning homework. All of them except California, Connecticut, New Jersey and Washington prohibit homework of some kinds (usually the manufacture of clothing or tobacco products or both) done by persons other than the immediate members of the family. Michigan forbids industrial homework altogether in the clothing and tobacco industries. All of the states except Ohio also have some sort of law regulating homework. Missouri requires only the registration of persons so employed, Tennessee demands sanitary conditions but permits work without a license, and Connecticut asks that the commissioner of labor be notified but

does not insist upon a license. Some states have made provisions for regular inspection; New York, for instance, requires all tenement houses used for manufacturing to be inspected once every six months. But in most states there are not enough inspectors to insure proper enforcement of the laws.

Social legislation in Germany, where homework also constitutes an important problem, is concerned with both sanitary conditions and wages of the homeworkers. The health regulations safeguard the worker's own health in the form of insurance against sickness and restrictions concerning work on incendiary or unsanitary goods and, on the other hand, prohibit homework on such goods as bakery products, the production of which even if undertaken under "normal" home conditions may constitute a menace to the consumer. Furthermore, hygienic working rooms are required. Wages come under the jurisdiction of trade committees, the *Fachausschüsse*. There are fifty-seven such committees; one of them comprises the whole of the industry producing carnival and similar paraphernalia; the other committees are concerned with portions of the various industries. In the clothing industry, for instance, twenty-seven committees operate; in the textile industry there are ten. In the main the trade committees regulate wages, chiefly by fixing hourly minimum rates, although if possible they also determine piece rates with due regard to working time.

The most thorough regulation of homework is found in Russia. The Russian homeworker shares the benefits provided by the advanced social legislation of the country. Wages, fixed by collective agreement with labor unions, are in keeping with the factory wage standards; and a minimum wage is fixed by the state. It happens not infrequently that the same collective agreement which covers the factory workers also applies to the homeworkers in the same industry. Membership in labor unions is virtually universal among homeworkers.

The problem of protecting the homeworker from the evils of sweatshop conditions has not been solved in thirty years of discussion. Direct control of homework may require that the houses in which work is done be licensed or that the employer register all his homeworkers. But the licensing system may be unfair to the worker if his trade is irregular and he has to secure a new license for each work period; moreover it cannot destroy child labor, which is so easily concealed. Registration is certainly desirable, but it must be

accompanied by adequate inspection of the homes; this up to the present has been lacking. Indirect control of homework through general social legislation is equally faulty. Hours cannot be regulated when the work is performed during leisure time or on rush orders. The fixing of wage rates by boards if completely effective would probably destroy homework entirely and leave without means of support many persons incapacitated for factory labor. Only if a whole industry is included under regulatory wage acts, as is the case under the English trade boards, can discriminatory legislation resulting in the complete destruction of homework in favor of the factory system be avoided. Most of the evils of homework are inherent in that type of work. If those evils are to be abolished, then homework itself must be abolished; the factory worker must have an income high enough to support his family without the assistance of his children, and incapacitated persons unable to do factory work must be taken care of by society.

HOMEYER, KARL GUSTAV (1795-1874), German jurist. Homeyer was born at Wolgast, a port of western Pomerania, which at that time belonged to Sweden; at an early age he came to Berlin. He studied at the University of Berlin under Savigny and Eichhorn, who strongly influenced him, and later became professor in this institution. After 1845 he also served as a judge of the supreme court at Berlin and after 1854 as a member of the Prussian upper house.

Homeyer's principal activity as a jurist was dedicated to the Germanic law books of the Middle Ages, particularly to the editing of the famous *Sachsenspiegel*. His edition of its first part containing the *Landrecht* (Berlin 1827, 3rd ed. 1861) is still of basic importance. There followed the editing of its second part with the related texts, *Des Sachsenspiegels zweiter Theil nebst den verwandten Rechtsbüchern* (2 vols., Berlin

1842-44). The first volume contained the *Lehnrecht*, or feudal law, with its accompanying procedural law, the *Richtsteig Lehnrechts*; the second contained the *Auctor vetus de beneficiis*, the *Görlitz Rechtsbuch*, both versions of the *Sachsenspiegel*, and a systematic treatment of the feudal law. The editing of the *Landrecht* procedural law was later published as *Der Richtsteig Landrechts* (Berlin 1857). Various problems and controversies led Homeyer to a long series of essays which also took their point of departure from the *Sachsenspiegel*. In a second group of works, however, he dealt with the problem of distinctive family symbols or badges. The research of several decades was finally embodied in *Die Haus- und Hofmarken* (Berlin 1870). He also wrote brilliantly in the general field of Germanic law in "Das Recht des Dreissigsten" (in *Königliche Akademie der Wissenschaften, Berlin, Philologische und historische Abhandlungen*, 1864, p. 87-270), in which he treated the old Germanic custom of allowing the relatives of a deceased ancestor to remain in undisturbed residence in his house for thirty days—a custom moreover which Homeyer traced back into Jewish and ancient law. He had shown his interest in northern law as early as 1824, when he began translating Kölderup-Rosenvinge's history of Danish law.

In his handling of texts Homeyer showed critical acumen and precision extending even to insignificant detail as well as scholarly caution and restraint in the elucidation of particular points. He was thus a true adherent of the historical school, standing in close spiritual relationship to his teachers, Savigny and Eichhorn, and to Jacob Grimm.

CLAUDIUS VON SCHWERIN

Consult: Stintzing, R. von, and Landsberg, E., *Geschichte der deutschen Rechtswissenschaft*, 3 vols. (Munich 1880-1910) vol. iii, pt. ii, p. 311-15, 525-30.

HOMICIDE is the killing of a human being. Such a neutral term must be considered an obvious necessity in view of the fact that homicide may be made punishable with reference to a great number of mental elements as well as to external circumstances. The mere possibility of this should make it plain that there has never been a universal concept of wrongful homicide. The history of homicide shows little indeed that is axiomatic. Even in the historical period it has not always been treated as a public crime, and the blood vengeance feud and composition for homicide have not become entirely obsolete in modern times. A horror of homicide is a modern

phenomenon. As heresy and treason have been the great crimes of theocratic and monarchic society, homicide is the great crime of democratic, secular and individualistic society, which has elevated man to a position of supreme dignity. But this of course is not to say that church and state have been indifferent to the security of human life. Its protection becomes very soon one of the chief objectives of the organized state. Moreover in the discrimination of the degrees of guilt in homicide religious influences have played a very great role.

Among the peoples of antiquity who have most influenced western civilization the Hebrews show most clearly the traces of the conception that homicide is only a private wrong. The specific prohibition of the Pentateuch, "Ye shall take no satisfaction for the life of a murderer" (*Numbers xxxv: 31*), must obviously have been directed against a once prevailing practise of taking blood money, although by this time homicide had come to be conceived as a crime against the whole community, which might be polluted by the bloodguilt of the murderer. The provisions for the cities of refuge, to which the accidental slayer might flee, imply the existence of courts which were competent to make distinctions between homicides. It is interesting that the tests, as they tend to be in all primitive law, were largely circumstantial. The Pentateuch enumerates the circumstances of lying in wait, ambushing, the existence of enmity or hatred on the part of the perpetrator, guile, the procuring in advance of means of homicide. The most fundamental distinction perhaps is one that has significantly a theocratic tinge, that between searching the victim out and waiting for God to deliver him into the slayer's hands.

The treatment of the history of the Greek law of homicide has been almost completely overshadowed by the doctrine of pollution, which is already apparent in the Pentateuch. The famous trial scene on the shield of Achilles probably bespeaks a purely private conception of homicide. The doctrine of pollution did not become established until the latter part of the seventh century with the introduction of the cult of Apollo. While the idea of pollution thereafter played a very great role in Greek life and thought, it is wrong to regard it, as has often been the case, as the central force in the creation of Greek criminal law, which as elsewhere must have grown under the impetus of political necessities. The apparent overemphasis of homicide in Greek law may well be ascribed to the fact that

only the provisions of the code of Draco relating to homicide have remained extant. An even greater source of misconception has been the Erinyes of the Greek tragic dramatists. These hardly expressed the normal Greek attitude toward pollution.

The Greek law of homicide is also peculiar in its development of a multiplicity of special courts. The jurisdictions of these homicide courts indicate the Greek distinction between punishable homicides. The Areopagus, reputed to be the most ancient homicide court in Greece, was probably the body from which the other courts had developed, doubtless by a process of subdivision. It had jurisdiction of the most serious cases of homicide—voluntary homicide, wounding with intent, poisoning—and arson. The court of the Palladium judged involuntary homicide and the slaying of non-citizens. To the court of the Delphinium were assigned cases of justifiable homicide. The court of the Phreato tried those who had committed a homicide while in exile for a former involuntary homicide. In order to avoid the pollution of Attic soil the defendant made his defense from a boat while the court sat upon the shore. The court of the Prytaneum sat in judgment over unknown slayers as well as over animals and inanimate objects which had caused the death of a human being. This practise of trying animals and things was very common everywhere in ancient times and lasted beyond the Middle Ages.

The Romans are remarkable in developing the concept of homicide as a public crime much earlier than any other Indo-Germanic people. *Quaestores parricidii* appear at a very early date. It is certain that homicide was a crime before the period of the Twelve Tables. Its scope is not exactly known but it constituted one of the two fundamental notions of the Roman criminal law, which were *perduellio*, applicable to acts of treason, and *parricidium*, applicable to acts of homicide. The relation of the two crimes must have been close; it can readily be imagined that to kill a Roman citizen would be regarded almost as an attempt to subvert the safety of the state. *Parricidium* as a special crime of killing a parent or other close relative has been handed down by the Roman law to the modern continental codes, but in early Roman law it had no such significance. The process by which *parricidium* came in effect to be *patricidium* is very obscure, and most of the explanations are more ingenious than convincing. The punishment for parricide was originally the terrible one of the *culeus*, but al-

though abolished in Roman law by the *lex pompeia de parricidiis* it was revived again in the Middle Ages.

The later Roman law of homicide was based on the laws of Sulla. The *lex cornelia de sicariis et veneficis* really covered a multiplicity of crimes. It is so particularistic in its terms that it must plainly have been occasional, directed primarily against the violence that was doubtless all too frequent in the republic. Whether it repealed and superseded the older law of *parricidium* is not clear. But it is certain that although by its terms it was applicable only to such crimes as assassination and banditry, it was soon stretched to cover every homicide committed or even attempted with violence. The special Cornelian delict of poisoning has, like parricide, also descended to the modern continental codes. Because of difficulties of medical diagnosis the crime was long associated with sorcery. In accordance with the general tendency of Roman law *dolus* had always to be shown, but it is not clear whether this meant premeditation as well as intention. Whether the Roman law even after Hadrian punished homicide committed with "criminal negligence" is disputed.

The conception of homicide as a public crime remained to some extent "imperfect" from the modern point of view among Hebrews, Greeks and Romans. The survival of the blood vengeance feud may be seen in the Hebrew practise of delivering the convicted murderer into the hands of the victim's nearest relative, the "avenger of blood," for execution. Among the Greeks only the relatives could institute the proceedings in the homicide courts, a practise which remained unchanged even after the reforms of Solon, who introduced the novelty of allowing any Athenian citizen to institute a public action. The Roman law of homicide did not protect slaves until very late in its history. The prominence of the privilege of exile in the ancient law may bespeak a memory of the time when expulsion from the group was the penalty for kin slaying. The Greeks allowed even the wilful slayer to go into voluntary exile. It was only when he chose to stand trial that the penalty of death was inflicted. Voluntary exile became permissible also among the Romans in the republican period and was converted into deportation only under the empire.

The homicide law of the Germanic folk laws is particularly important for an understanding of the development of western law. It is to the Germanic conception of the most aggravated

form of homicide that modern law owes at least the name murder. The Germans, a warlike people, looked upon a homicide in an open fight between two armed men as involving no disgrace. On the other hand, a secret homicide was dishonorable. *Mord* meant secret slaying but was applicable also to other wrongs; thus *Mordbrandt* meant secret arson. Literally, the slayer "murdered" the dead body by concealing it. The punishment for secret homicide was three times the ordinary *wergild* among the Franks and Frisians and nine times among the upper Germans and Saxons. But in the northern laws homicide was counted an evil deed that made a man peaceless.

Even more important than the idea of the secret homicide, which did not long maintain itself, was a later Germanic idea. The Germans regarded as manslaughter any slaying without cause. But soon the deed of presumptuous rashness attracted special attention because under such circumstances the family would be less likely to forego the feud. The royal legislation of the Frankish period sought to deal with this situation. The punishment which was meted out for a homicide of presumptuous rashness became variously death or exile or total confiscation of property.

It is most important to remember that the Germanic folk laws had looked to the objective fact of injury. Their standards of liability if not absolute were certainly strict. The composition had to be paid not only for a homicide committed by misadventure but even for one in self-defense. When in the course of the thirteenth century homicide generally became a public crime—under special circumstances such as the violation of a special peace of lord, emperor, king or church it had become a public crime much earlier—the change was not accompanied by a very great degree of displacement of old ideas. The strict responsibility of the period of composition was well suited to the postmediaeval policy of savage repression; and in the main it survived, although the penalty for homicide had become capital. To be sure there were concessions. Homicide might now be committed generally in self-defense, although even in such a case it was still said that there was an "appearance" of crime. But accidental homicide might still involve a mitigated punishment. Any wounding which resulted in death made the assailant guilty of capital homicide; and in the Langobard and northern laws the death might ensue within a year and a day, a long period doubtless due to

the immaturity of medical science. Provocation would ordinarily be no excuse. To slay an enemy in a chance affray might be "simple" homicide, to lie in wait for him might be "deliberate"; but in either case the penalty was capital. The only difference was that it might assume a more comfortable form in the former case than in the latter. Thus under the *Carolina*, the penal code of the empire, the *fürsetsliche mutwillige mörder* was to be broken on the wheel, but the one who had *eyn todtschlag aus gecheyt und zorn gethan* was still to perish by the sword. As composition had pretty nearly always been due, the capital penalty was now almost always due.

The neo-Romanic period witnessed a gradual abandonment of the principle of objectivity, the most important enemy of which was without doubt the church. The church had never tended to treat homicide with the severity which it reserved for such a crime as heresy. In the Merovingian period it had favored the system of composition, although by the Carolingian period it confined itself to eradicating private revenge and securing recognition of the right of asylum. In the later public war on homicide the church could not but help to make subjective distinctions between offenders. It was concerned with moral responsibility, and hence the animus of the offender. The revived Roman law contributed the idea of *dolus*, which the Italian criminalists developed; but unfortunately *dolus* had to struggle with the idea of the deed of presumptuous rashness and its triumph was far from complete. There simply took place that unhappy marriage of convenience whereby the Germanic idea took the Latin name and became embodied in the concept of *dolus indirectus*, which dominated criminal theory after Carpzov. A provocation might excuse a homicide, but it might still be murder if the act of the accused showed a depraved mind.

The English law of homicide reveals the typical Germanic evolution, with the possible exception of the famous institution of the *lex murdrorum*, which is particularly interesting because it hints at the relation of homicide to conquest. Whether it was introduced by the Danes, to whom it had been familiar in their native land, or by the Normans or continued by Norman legislation is not certain. In any event, it was certainly an urgent measure for the protection of the followers of military adventurers in a conquered country. By the *lex murdrorum* a fine was imposed by the king upon the hundred when a man was slain and it could neither produce the

murderer nor by the so-called "presentment of Englishry" prove that he was an Englishman. Other exceptions increasingly restricted the *lex murdrorum* up to the time of its final abolition in 1340.

What particularly distinguishes the English law is the longer survival in it of mediaeval Germanic ideas. The appeal of murder which gave the kin a part in the prosecution of the crime was not formally abolished until 1819. That some taint attached to almost every homicide is apparent in the distinction between "justifiable homicide," as in self-defense, and "excusable homicide," as by misadventure. Throughout the later Middle Ages the man who slew another by accident had to procure the king's pardon, and the forfeiture of movable property which followed in such a case was not formally abolished until 1828, when the distinction between justifiable and excusable homicides ceased to have any meaning in English law. Moreover the old rule that a wounding which resulted in death within a year and a day was murder is still theoretically in force in English law today.

The present English law of homicide thus still harbors the concept of *dolus indirectus*. Its prevailing test of murder is the well known "malice aforethought," a special phrase primarily due to the accident of its use in the statute, 23 Henry VIII, c. 1, which took away benefit of clergy in the case of "murder of malice aforethought." But this malice may be either express or implied; in other words, there may be neither malice nor forethought. A homicide committed according to a preconceived design will of course be murder, but so will a homicide committed intentionally but on a momentary impulse or recklessly or in the course of the commission of a felony. Murder is distinguished from manslaughter, which in English law is either voluntary or involuntary. It is voluntary when done in the heat of passion upon gross provocation; and involuntary when committed unintentionally in the performance of some unlawful act which does not amount to a felony and is unlikely to endanger life or when it results from negligence in the performance of some lawful act or from the omission to perform a legal duty. The distinction between murder and manslaughter sometimes becomes very tenuous. That the English law does not lead to a needless severity in many cases is due only to the powers of intervention of the home secretary.

Intent triumphed all but completely in the continental codes of the early nineteenth cen-

tury which, dominated by a philosophical individualism, erected the determination of the will into a guiding principle of legal liability. Thus crimes of homicide became differentiated into various kinds of intention. Premeditation became the prevailing test of murder. Simple intention became the prevailing test of manslaughter. If a homicide might still be committed with negligence, it was now only a comparatively minor crime which entailed a light penalty. But the particularistic delicts of the Roman law were generally retained in one form or another, *parricidium* and *veneficium* quite commonly, *latrocinium* much less frequently.

Upon this basis still rest the French and the German penal codes despite a considerable difference in terminology. *Mord* and *Totschlag* are murder and manslaughter in the German code; in the French code *meurtre* is not murder but manslaughter, while premeditated homicide is assassination, as indeed it is in all the Latin codes. But the more than six decades of criminological advance that separate the French and the German code have resulted in some improvements of form and substance to the advantage of the latter. Thus *guet apens*, or waylaying, is especially mentioned in the French code, but since this would clearly fall within the rule of premeditation it must be regarded as superfluous and has indeed become practically obsolete. Parricide, which is a special capital delict in the French code, has become simply an aggravating circumstance of manslaughter in the German, which also has converted poisoning into a general delict. The German homicide provisions are much simpler because greater reliance is placed upon generalization. Since an insult to honor is a possible provocation under the German code, it is not necessary to make specific provision, as in the French code, for the slaying of an adulterer taken by the husband in *flagrante delicto*, a common provision in the Latin codes. While under the French code such a homicide is entirely excusable, the tendency under more recent codes has been to impose some degree of punishment and sometimes to extend the privilege to the wife. Thus too self-defense has been erected into a general doctrine in the German law, while in the French it is specially defined in connection with homicide. The German code is milder than the French in its treatment of a homicide in the course of the commission of a criminal act. Not only is it not a capital offense as under the French code, but there must be an inner connection of purpose with the crime that

is being committed. The drafters of the German code also made murder upon request of the victim a lesser form of manslaughter, an exception which exists in a less general form in many codes which mention it in connection with suicide. The Austrian law curiously differs quite fundamentally from the German. It is still dominated by *dolus indirectus*.

The codes of the Latin countries which have been based largely either upon the Spanish or Italian codes differ from both the French and German in respect of a far greater degree of particularism. In both the old Spanish code of 1870 and the new one of 1928 premeditation is still a constitutive element which converts homicide into assassination. But so will a variety of four other circumstances: treachery; the hiring of an assassin; the resort to submersion, arson or poison; or the presence of barbarism in the execution of the deed. The new code is even more particularistic. The same characteristic is to be seen in the Italian code of 1889, which, however, took the further step of abandoning premeditation altogether as a constitutive element. The generic crime is homicide with intent to kill, and premeditation is simply one of the list of aggravating circumstances. In one stage of the drafting of the new Italian code of 1931 premeditation was omitted altogether even as an aggravating circumstance, but it was finally restored as such. Premeditation is not, however, among the aggravating circumstances which will entail capital punishment but among those leading to life imprisonment. The same course has been taken by the new Turkish penal code of 1926, with the difference that premeditation involves the death penalty.

It is held to be one of the commonplaces of Anglo-American legal history that American law represents only an adaptation of English legal institutions. It is thus interesting to note that the steady tendency in American codes has been away from the English law of homicide, which is now accepted in only a few states. The present American law is far more closely affiliated with that of the European codes of the nineteenth century. The process began as early as 1794 with a Pennsylvania statute which divided murder into two degrees. Both murder and manslaughter are now commonly divided into degrees. In murder in the first degree premeditation is emphasized. To kill in the course of the commission of such serious crimes as arson, rape, burglary and robbery is also commonly murder in the first degree. Thus the general felony rule of the

common law has been abrogated. The concept of manslaughter is frequently characterized negatively by the absence of intention and positively by the presence of provocation. In its frequent particularism, which indeed is a general characteristic of American criminal law, the American law of homicide also has a great deal in common with the European.

Certainly to the Anglo-American it may seem almost a gross impiety to question the usefulness of the concept of premeditation as a test of murder. If the German law of homicide, which still retains it, seemed to Sir James Fitzjames Stephen, the leading historian of the English criminal law, "singularly defective"—Franz von Liszt once returned the compliment in commenting on the arrested development of the English law—the newer codes would certainly appall him. To a system of criminal law based upon the idea of moral responsibility premeditation may be admitted to be fundamental. But to a system based upon the idea of social defense it is not a very useful concept. For it needs little reflection to show that a misguided idealist who kills with premeditation may be far less dangerous to society than the armed desperado who kills upon momentary impulse. A favorite example among the positivist criminologists is the murder of Caesar by Brutus. The very fact that there is a struggle of impulses in the murderer shows that he is less of a menace to society. It is motive that is all important. The newer codes are still far from the more advanced positivist position. But at least the relegation of premeditation to the categories of aggravating circumstances should have the merit of excluding its operation as a basis of complicity. For when so relegated it should become a purely personal attribute of guilt to be proved against each participant in the crime. The objection to multiplying aggravating circumstances is that they lead again to the old particularism, which has been proved to have a tendency to lead to hardship in particular cases. There is also the danger that certain circumstances will become anachronistic. Yet as long as the death penalty is retained, it is imperative that some limitations upon penological treatment exist.

The most complete break with western tradition is represented by the penal code of Soviet Russia, in which homicide has ceased to be the major crime. The normal penalty for intentional homicide is eight years of solitary confinement. The aggravating circumstances which will increase the period of incarceration to ten years

are the presence of dishonorable motives, such as greed and jealousy; recidivism; and the existence of a special duty to care for the victim. Parricide is not specially mentioned. Among extenuating circumstances are mentioned provocation and the overstepping of the bounds of necessary self-defense.

There are a great many statistics upon the frequency and distribution of homicide but they are not to be too implicitly trusted. It is more difficult to determine the criminal character of a homicide than of any other act, for, as the old adage has it, "dead men tell no tales." Thus tables based upon homicides known to the police may be very different from those based upon judicial or census records. Insurance company figures may diverge from both. Again, the variance in the legal conceptions of murder and manslaughter affects the comparability of the court statistics for different countries. Moreover, even where legal conceptions are the same, the basis of compilation may cause difficulties. Thus infanticide may be included. Germany apparently has even included legal executions in deaths due to homicide. It follows that unless the rates are considerably higher in one country than in another it is unsafe to draw too definite conclusions.

The homicide rates in European countries showed a fairly steady decline before the period of the World War. According to a table drawn up by Ferri homicides in Italy diminished in relation to 100,000 population from 12.2 in 1871-75 to 4.1 in 1911-15; in France, from 2.4 in 1827-31 to 0.44 in 1911-15; in England, from 3.1 in 1856-60 to 0.7 in 1906-10; in Germany from 1.0 in 1865-85 to 0.6 in 1906-10; in Spain from 9.4 in 1881-85 to 5.2 in 1911-15. Generally the northern European countries have shown far lower homicide rates than the southern. This is probably to be ascribed rather to the forms of social and political organization in these countries than to racial temperament. No statistical correlation has ever been established between homicide and climate.

During the war period itself the homicide rate in the belligerent European countries was very low, particularly during the first year of the war, a fact doubtless to be attributed to the subjecting of the male population to military discipline. After the war, however, with the exception of England there was a marked increase. The habitual population to killing effect, but the disorderly circumstances under

which demobilization was carried out in some countries as well as the post-war social and political unrest were probably the far more important factors.

The post-war rise in homicide has been said to be particularly striking in the United States. According to Hoffman, who has been the most diligent gatherer of American homicide statistics, the rate for thirty-one cities with a collective population of almost 25,000,000 in 1930 rose from 5.1 per 100,000 in 1900 to 10.9 in 1930. According to the Bureau of the Census the homicide rate rose from 6.5 in 1912 to 8.5 in 1929. The Wickersham Commission estimated 8720 homicides for the whole country during 1930. The situation seems even worse when the small proportion of convictions in homicide cases is considered, although with regard to this it must be remembered that in most countries the ratio of convictions to accusations is normally less for homicide than for other crimes. An examination of the homicide rates of the different sections of the country shows that the New England states have the lowest rates, while the southern states have the highest. This is in line with the homicidal tendency of southern countries, but the rates of the American southern states are particularly high because of the presence of large Negro elements in their populations. The statistics generally establish far higher homicide rates for Negroes than for whites. A survey by Brearley shows indeed that it is almost seven times more than for whites. Moreover the proportion holds in both north and south and in both urban and rural areas. It is not definitely established to what extent Negroes are slain by whites. It is certain, however, that racial antagonism resulting from oppression and not innate racial traits is primarily responsible for the situation. In any event, this situation accounts in large measure for the fact that American homicide rates are so high. Contrary to popular conception, it was neither New York nor Chicago but Memphis that had the highest homicide rate in the country in 1930. The figures are per 100,000 population 7.1, 14.4 and 58.8 respectively. It should be observed that there is no necessary correlation between urbanization and high homicide rates. In the United States in recent years rural rates have occasionally exceeded the urban. Great metropolitan centers like London or Berlin have shown very low homicide rates.

The fundamental causes of homicide are highly complex. It is interesting that while criminolo-

gists have been able to show some very striking correlations between many crimes and economic conditions, they have been unable to do so with respect to homicide. Indeed manslaughter may be more common in good times, since prosperity favors the general ebullition of spirits which often occasions these crimes. Of course this is not to imply that social factors do not play a great part in the causation of homicide. It is simply to say that it is not directly connected with economic want. This is obvious enough when one considers the extent to which homicides are "crimes of passion." That mental abnormalities are very frequent here may be readily granted. Perhaps every murderer is at least temporarily insane. But to attempt to find the typical murderer is to pursue a phantom.

The best statistical sources are of course the official governmental tabulations where these are available.

HONOR represents a strong personal sense of socially accepted dignity or socially expected conduct. It is this consciously double aspect which distinguishes honor from other ethical attitudes. Conduct is the basic neutral stem from which all moral attitudes spring. Character is systematized and regularized conduct. Conscience is the deeply internalized acceptance of a moral order. Etiquette is the lightly externalized acceptance of social control. Honor is an open acknowledgment of external demand but an acknowledgment which through pride has become enthroned in the very citadel of the self. It combines thus the urgency that etiquette carries for the cultured with the exaction which conscience carries for all—combines them in a self-respect which bridges the moral dualism between external and internal sanctions. In this way honor represents the goal of character formation and an instrument of social control; it forms the best basis for predicting conduct; for it connotes an individual's wanting to be and do what others want him to be and do. It is impossible to appraise, however, the extent to which honor stays or facilitates moral progress. Representing as it does expected conduct, honor strongly tends to maintain at a high level the morale of the status quo.

But the status quo must be pluralistically conceived. Inside any given group there are other groups; and the same psychological technique which contrives the dominance over the individual of large scale expectedness prescribes the even more intimate emotional acceptance by the individual of small group influence. This guarantees not only that codes of honor will change with changing cultures but that they will reflect the variety of the social structure at any given time and place. Each individual may have different senses of honor to answer to his variegated social contacts—in the family one code, in business another, in politics still another. A man may be a proudly good father and at the same time a sternly successful racketeer or a mean spirited family man and a generous social engineer in business. A woman may protect with her life her honor against alien advances and yet maintain the honor of her home by submitting without life or love to the sexual advances of her husband. She may protect the honor of her own children by means that limit crucially the opportunities of other children. Social evolution does not advance with equal pace along all fronts, and every lag will represent not the absence of but a discrepancy in honor.

With social mobility, however, variety in honor codes is made more difficult to maintain. Incompatibles that never contact may easily be maintained by compartmentization; but where logical incompatibles are easily and necessarily juxtaposed, their incompatibility is likely to lead to physical readjustment. A sense of humor arises, and a Don Quixote is born; or sober criticism becomes habitual, and a generalized code arises to harmonize and to supplant previous codes. A man becomes "a Christian gentleman" or "a good citizen" (generalized norms), to the making of whom will go not only prescription of idealized conduct in all his separate spheres but at least some minimum presupposition of consistency of each activity with all the others. The imperative demand made in the name of efficiency for a more or less integrated character is at once the explanation of this tendency in modern life and the guaranty of its persistence. The more generalized the ideal, however, the less emotionally poignant and perhaps the less practically effective it is. Indeed this generalized sense is likely to be called conscience or responsibility rather than honor. The notion of honor shows a strong affinity for either small groupism or for incompletely rationalized larger social perspectives. Illustrating the latter

in connection with national honor, George Herbert Mead remarks that "the only issue involved in the Monroe Doctrine is this, are you a patriot, are you a red-blooded American, or are you a mollycoddle?" Illustrating the former, we may turn to the origin of codes of honor in simpler societies.

The differential dominance of the group in primitive societies was made possible by the greater degree and sameness of social incidence upon the individual. Wherever differentiation of function arose, there was a new code; and since in the absence of substitute attraction or opportunity for expression it was accepted by all, it was a code of honor. Rules governing contests, combats, hospitality, heterosexual association, were the insignia of that inner sense which is honor. Honor might require a Lot under the rules of hospitality to sacrifice the virtue of his daughters; or a Jephthah under the obligations of religion the life of his child. On the other hand, honor might permit a Jael, having fulfilled the gesture of hospitality, to drive a tent pin through the head of the sleeping Sisera. Such primitive prescriptions as survived the struggle among codes precipitated by conquest and followed by group expansion constitute the dominant antecedents of our current standards of honor. The major ones are put together, however imperfectly, in the phrase "Christian gentleman." The Christian sense of honor prescribing inflexible devotion to the outcast group's perfectionistic code regardless of what other men might say or think or do was one thing—a significant enough thing to take men gladly to the stake. The Teutonic customs which accepted Christianity as tutor until they mastered it were another. The feudal aristocracy of Europe, with its mixed ideals of chivalry, of chastity, of the sanctity of private property—this is the background of our codes of honor. One thing arises as prescribed on Sunday, another on Monday; and but for the drift already alluded to in the name of business efficiency and mental hygiene one notes little organic unity between codes of honor and norms of social welfare. There is "honor among thieves"; and the rigor with which racketeers adhere to their code even when death offers immunity from vengeful fellows indicates that social expectation has here passed into genuine personal acceptance. Compulsion has become honor. And this honor of racketeers is a more hardy growth than the loyalty that citizens feel for the law set over against, but not therefore set over, the antisocial group.

One reason for the differential effectiveness of antisocial honor is that it is born of hostility to the larger and more powerful group and is enforced with sanctions extraordinarily stern and certain. In this way the modern outlawed group achieves something of the homogeneity of the primitive group. Wherever punishment can be certain and sure, conformity will arise and be transformed in favorable cases into loyalty. Ostracism was certain and terrible when ungrouped men had no rights. The feud operated in the same exclusive situation. Fear of being turned over to the "law" has all the rigor of these ancient sanctions for modern groups whose rights are largely extralegal. In so far as hostile impulses are accompanied by intenser emotions the honor of the racketeer is more effective than that of the citizen. Libel laws and breach of promise suits are not such safeguards of honor as were the duel and the shotgun. And because of the lesser effectiveness of legal remedies there is a tendency to recognize other means as legitimate where the sense of honor persists. The unwritten law is the law written in the hearts of men, to protect the code of honor that the law itself not only does not protect but which it even tends to dissipate through the substitution of tolerance and the dilution of hotly felt loyalties.

The sense of personal dignity which honor acknowledges and protects transfers itself to whatever one can easily become identified with: the family, the school, the profession, the nation. Whatever social entity can best foster hostile impulse can most easily appropriate the honor motif. The national state has a peculiar advantage here. Generated through struggle, maintaining itself by hostile gesture if not by hostile acts, it even becomes personalized with an honor all its own. Chauvinism, negatively, and imperialism, positively, thrive upon its touchy dignity; and the sense of honor becomes thus the one great obstacle in the way of international organization and function. Honor cannot be arbitrated, because "when honor's dead, the man is dead." Honor cannot be arbitrated, but it can be vindicated; apologies, wars, indemnities, are the instruments for its protection.

HONTHEIM, JOHANN NIKOLAUS VON (1701-90), Catholic prelate and theologian. Hontheim was ordained priest in 1728, was appointed professor at the University of Treves, held office under the archbishop of Coblenz and in 1748 became suffragan bishop of Treves. Although he had earlier written voluminously on the history of Treves, he became famous only after publishing, under the pseudonym of Justinus Febronius, *De statu ecclesiae et legitima potestate romani pontificis* (Frankfort 1763, 2nd ed. 1765). Febronianism, as his position soon came to be called, reflects the direct influence of van Espen, under whom he had studied at Louvain. It was a revival or extension of the episcopalism which had been advanced against curialism during the conciliar movement and at the Council of Trent and which had regained immense prestige in France during the seventeenth century when episcopal Gallicanism became merged with nationalist sentiment. Hontheim not only declared the pope to be inferior to the general council and superior to other bishops merely in magnitude of dignity but demanded the virtual independence of all national churches. He summoned the secular powers as well as the church to participate in effecting a reorganization conformable to these theories.

De statu was placed on the Index in 1764 and was vigorously attacked by a number of ultramontane writers, to whom Hontheim replied in three additional volumes published between 1770 and 1774. His identity soon became known, but for a number of reasons the pope could not take vigorous action against him. Hontheim had the favor of the archbishop of Treves, one of the electors of the Holy Roman Empire. Moreover the pope's influence had been greatly diminished by the spirit of the Enlightenment and by the various recent movements to extend the power of the state at the expense of the church.

Hence although Hontheim finally gave the church his formal retraction in 1778 he continued to assert his position without essential alteration, as is shown by his *Commentarius in suam retractionem* (Frankfort 1781). Being so well in accord with the tendencies of the time Febronianism exercised considerable influence not only in the German states but in the Latin countries as well. In 1769 the archbishops of Mainz, Treves and Cologne embodied its principle in a program which they renewed at the Congress of Ems in 1786, this time in conjunction with the prince-bishop of Salzburg. Febronianism was also one of the factors responsible for the church policy of Joseph II. After the turbulent interlude of the revolutionary and Napoleonic periods a totally different tendency became dominant in the church as a result of the Restoration and the rise of romanticism. Occasional echoes of Febronianism were, however, still heard in the works of Ignaz von Wessenberg and others.

HOOKE, RICHARD (1554-1600), English ecclesiastic and historian. Hooker's *Of the Lawes of Ecclesiasticall Politie* (bks. i-v, 1594-97; bks. vi-viii first published 1648) has become not only the authoritative defense of the English Reformation settlement but also a classic of English literature. His independence of judgment had made him reject the slavish cult of Calvin which characterized the Puritan movement in Elizabethan England, before his nomination to the mastership of the Temple brought him of necessity into the public controversy on that subject. There he realized the need of a thorough examination of the issues which divided Episcopalian from Presbyterian and resolved to undertake the statement of the Anglican position, not upon ephemeral and superficial points but upon the fundamental principles of civil and ecclesiastical society. The Puritan position (based on the conviction that Scriptural revelation, especially the New Testament, had declared all things necessary to human knowledge

and life—in state as well as in church) repudiated the conception of the identity of church and state which underlay the Tudor Reformation and gave to the sovereign an ecclesiastical administration as supreme governor of the Ecclesia Anglicana. In combating this position Hooker necessarily went behind the Puritan adherence to the word of Scripture back to first principles as expounded by the mediaeval schoolmen, particularly Thomas Aquinas. He insisted on the wide spheres of human life which were ruled not by express precept of revelation but by the laws of nature and the reason of man, implanted by the Creator and therefore of equally divine origin and authority with the Bible. His careful survey of the various kinds of law as well as of its universal sway caused him to abandon the narrow and restricted notion of divine legislation entertained by his opponents. His own political predilection was for constitutional monarchy based upon an implicit contract although the text thereof might have perished, but he did not claim for this form of government divine prescription to the exclusion of other forms. Maintaining that in a Christian state the members of the body politic were identical in number and person with the members of the church, Hooker regarded the alliance of monarchy and episcopacy not only as a perfect theoretical expression of the essential unity of church and state but as a sound practical agent of moderation and constitutional government. To Hooker the English Reformation was not an innovation, but a reform; and both in church and state he rejoiced to build upon the foundations of human experience in the past, free from the restriction of outlook and extremism which hampered both the Puritan and the champion of Tridentine papalism.

W., *A History of Political Thought in the Sixteenth Century* (London 1928) p. 184-98, 239-41; Pearson, A. F. Scott, *Thomas Cartwright and Elizabethan Puritanism, 1535-1603* (Cambridge, Eng. 1925).

HOOKE, THOMAS (1586-1647), English-American Puritan divine. Hooker was educated at Cambridge and became a conspicuous leader

of dissent in Essex. Fleeing from Archbishop Laud in 1630 he took refuge in Holland and then in Massachusetts Bay in 1633. For reasons which are still obscure he became dissatisfied with the regime there and in 1636 led four congregations into Connecticut. He was the dominating figure in the colonies established there, directing their policies and expounding their religious and political creed. Since the settlers possessed no charter nor any prearranged government they turned to the models of rule already familiar to them in Congregational polity. Just as the assembled Christians drew up a church covenant, so they framed their political organization in a formal document, *The Fundamental Orders of Connecticut (Old South Leaflets, general ser., vol. i, no. viii, Boston 1896)*, known as the first written constitution in America. Hooker's own principles were most clearly expressed in a sermon of 1638; this is a clear instance of the application of Congregational ideas to politics, and subsequent generations have probably overemphasized its democracy. It lays down explicitly the doctrine that the choice of public magistrates belongs by God's allowance to the people and that the people who appoint officers can also "set the bounds and limitations of the power and place." But Hooker insured these principles against popular abuse by insisting that the people could exercise their power not according to their humors but only according to the will and law of God, of which of course Hooker was the supreme interpreter in Connecticut. Although the *Fundamental Orders* did not confine the franchise to church members, the Connecticut clergy retained sufficient moral force to keep the colony hardly less a theocracy than Massachusetts. Nevertheless, in sharp contradistinction to the theory of the Massachusetts rulers, which claimed for magistrates a wide discretionary freedom, Hooker's philosophy is significant for its marked insistence upon the responsibility of elected officials to the constituency and to the fundamental law. He applied the same democratic approach in his views concerning church government. His *Survey of the Summe of Church Discipline* (London 1648) is the most vigorous statement of the Congregational, or Independent, attitude, as opposed to the Presbyterian, with regard to the Puritan polity.

Hill as *The Rise of Modern Democracy in Old and New England* (London 1894) p. 117-41; Walker, Williston, *Creeeds and Platforms of Congregationalism* (New York 1893) p. 139-48.

HORN, EDUARD IGNACZ (Einhorn) (1825-75), Hungarian economist and publicist. The son of middle class Jewish parents, Einhorn studied the Talmud abroad and philosophy at the University of Budapest. He wrote for the liberal press and from 1848 until its suppression in 1849 edited a weekly, *Der ungarische Israelit*, devoted chiefly to Jewish religious reform. He served as rabbi of the Pest reform community and as Jewish chaplain in the Hungarian revolutionary forces during 1849. With the collapse of the revolution he fled to Leipsic and to evade persecution changed his name. He wrote several books on Hungarian politics, one of which, a life of Kossuth, was suppressed at the demand of the Austrian government but in an English translation stimulated much sympathy for the revolution. In Leipsic Horn attended Roscher's lectures and became interested in economics, particularly questions of credit. After a stay in Brussels he settled in Paris in 1852, where he engaged in journalism, especially for the then liberal *Journal des débats* and in defense of the Hungarian revolution. He produced a number of scholarly works on economic history, financial policy and especially credit. His book advocating freedom of banking, which attracted much attention and was translated into German (Stuttgart 1867) and Hungarian (Budapest 1870), is not only a notable contribution to the study of banking but also a fundamental treatment of the entire problem of money. Horn attacked the fiat theory and the view that money is a symbol without real value; he tried to prove the commodity nature of money. He advocated a self-help program for workers, helped organize trade union credit banks in France and Belgium and proposed an international congress of cooperators. He returned to Hungary in 1869, became deputy in 1872 and minister of commerce in 1875. Horn is perhaps the leading Hungarian representative of the type of liberal mid-nineteenth century Jew, of whom Riesser in Germany and Crémieux in France are other instances.

HORNIGK, PHILIPP WILHELM VON (1638-1712), Austrian cameralist. Hornigk studied law in Ingolstadt and entered the service of Cardinal Lamberg of Passau in 1690. He early attained distinction as a political writer. Published under the name of H. G. D. C. (*Hippophili Galeacii de Cornelii Francopolitae*), his political writings were directed chiefly against the territorial claims of France and attempted to establish the rights of Germany to the heritage of Charlemagne; he advocated the use of force in wresting Alsace-Lorraine from France.

Hornigk's chief work, however, was *Oesterreich über Alles, wann es nur will* (n.p. 1684, later ed. Regensburg 1723). In this book he undertook to formulate an economic policy which aimed to render Austria economically self-sufficient and to raise her position above that of all other countries. This truly mercantilistic program called for a complete investigation of the country's resources, the utilization of all raw materials in domestic manufacture and a constructive population policy. Gold and silver must not leave the country. Imports should be confined to raw materials and paid for in goods. The importation of manufactured commodities ought to be strictly prohibited as "it would be better to pay for any article two thalers which would remain in the country than only one which would go abroad." A true mercantilist, he asserted the primacy of political aims over economic considerations; according to him the fundamental problem was the balance not of trade but of political power. His work attracted great attention and was of considerable influence in shaping the commercial policy of Austria in the eighteenth century.

HORTON, SAMUEL DANA (1844-95), American bimetallist and lawyer. During the years of bimetallic controversy from 1875 to 1895 Horton and Francis A. Walker were the leading American advocates of an international bimetallic coinage union as being the only means of solving the world's currency problems. In Horton's mind the wisdom of employing silver as well as gold as a standard coin had been demonstrated by historical developments. To those who pointed to the industrial supremacy of Britain as evidence of the superiority of a single standard Horton replied that for decades England's currency had been protected against pronounced value fluctuations only by the effective operation of the double standard elsewhere.

Much of Horton's work was done abroad and the scope of his publications pertained to currency developments in foreign countries as well as in the United States. In 1878 he was appointed secretary of the International Monetary Congress held in connection with the Paris exposition. Entrusted by the American secretary of state with the task of editing the conference reports, he annotated the actual proceedings and also secured the admission of many appendices containing valuable material for monetary study. Horton represented the United States at the Paris conference in 1881 and a year later at the request of the secretary of state visited European capitals to confer with foreign bimetallists regarding the advisability of reassembling the monetary conference of 1881. By this time he had abandoned the practise of law and devoted himself entirely to international bimetallism.

HORVÁTH, MIHÁLY (1809-78), Hungarian historian and statesman. Of humble birth, moving for many years as a member of the lower clergy among the Hungarian peasantry and small

bourgeoisie and later a private tutor in aristocratic families, Horváth whole heartedly embraced the liberal and democratic ideology of his generation which was to engage in a heroic fight against Hapsburg absolutism and feudal oligarchy. In 1844 he was nominated professor of Hungarian language and literature in the Viennese Theresianum, but later he was engulfed in the waves of the revolution and in 1849 was minister for religion and public instruction in the revolutionary government of Louis Kossuth. In this capacity he conducted an enthusiastic campaign among the lower clergy for separation from Austria and later for a crusade against the Russian invasion. After the collapse of the revolution he was sentenced to death by the imperial tribunal, fled and was hanged in effigy. Horváth is generally regarded as the founder of Hungarian history, which before him lacked the spirit of criticism and comparison and was largely devoted to a glorification of the past and an extolling of assumed national grandeur. Horváth opened a new road in his historical inquiries. He despised the nationalistic history of battles and kings and the old feudal slogan *Extra Hungariam non est vita*. His main interest was to show the social and cultural aspects of Hungarian history, its interdependence with the general European currents. During his exile in Brussels he collected all the documents relating to Hungary contained in the archives there and later published them in four volumes (*Magyar történelmi okmánytár*, Budapest 1857-59). His first work was dedicated to the history of Hungarian industry and commerce. Later he wrote practically the whole history of Hungary. His most significant achievements, however, were his *Huszonöt év magyarországi történetéből 1823-tól 1848-ig* (Geneva 1865, 3rd ed. Budapest 1885; tr. into German by Joseph Novelli as *Fünf und zwanzig Jahre aus der Geschichte Ungarns von 1823-1848*, 2 vols., Leipsic 1867) and *Magyarország függetlenségi harcának története* (History of the struggle for Hungarian independence, Geneva 1865; 3rd ed., 2 vols., Budapest 1881). Although his friends warned him that publication of the latter work would retard the royal amnesty for which he longed, he did not defer its appearance. In his treatment of the revolutionary period he tried to remain impartial toward both Vienna and the leaders of the Hungarian revolution. Horváth was not only a remarkable historian but by the force of his style and the vigor of his convictions he became a great educator for posterity. He can be regarded

as the representative in historiography of Hungarian liberalism and democracy.

Consult: Fraknói, Vilmos, *Emlékezés Horváth Mihály fölött* (Budapest 1879); Salamon, Ferencz, *Emlékezés Horváth Mihály fölött* (Budapest 1880); Márki, Sándor, *Horváth Mihály* (Budapest 1917).

HOSPITAL, MICHEL DE L' (c. 1504-73), French statesman. While a student of law in the University of Toulouse, L'Hospital was arrested and exiled by Francis I. He completed his legal studies in the University of Padua and occupied a professorial chair in civil law for two years in the former institution. In Italy he imbibed humanistic ideas, especially the belief in absolute government. Returning to France, he became one of the most erudite lawyers of his time. He engaged in politics, obtained a post in the Parliament of Paris and rapidly developed into a national figure.

As a statesman L'Hospital was an exponent of religious toleration and of a unified absolute monarchy. He was one of the first men in France to express the *politique* idea that the welfare of the absolute monarchy should supersede all other interests. Influenced by his humanistic training he believed that the antimonarchical tendencies of the religious wars had clearly demonstrated the necessity for toleration if France were to remain a consolidated state secure from foreign foes. As chancellor of France from 1560 to 1568 he endeavored to save the nation by solving the three outstanding problems threatening the monarchy. He tried to end religious divisions by advocating the principle of toleration, he curtailed the powers of the nobles and, finally, he planned to establish a uniform legal code and an organized system of tribunals. He was unable to carry out his policies and retired to private life in 1568, but he helped to pave the way for the development of the great French absolute monarchy of Henry IV, Louis XIII and Louis XIV.

HOSPITALITY is the custom of accommodating strangers in need of shelter, food and protection. Among primitive peoples it is found in a

pronounced form among agriculturists, less among hunters and pastoral peoples. It does not arise from a spontaneous feeling of sympathy, but is regulated by tradition among definite kinship groups and later among definite individuals and entire tribes. All strangers who stand outside the circle of friendly relationships regulated by tradition and by the principle of reciprocity are considered as enemies. Hospitality relations among hunting peoples are illustrated by the customs of the Bergdama in Southwest Africa, where a traveling stranger is furnished shelter and food. The chief of this tribe formerly also permitted the stranger to have intercourse with one of his wives; such sexual hospitality, offered preferably to members of the kinship group, is found among many primitive peoples. Among agriculturists, such as the Polynesians, hospitality assumes at times a decidedly sympathetic, chivalrous character; hospitality and liberality are imperatively demanded by public opinion among the Maori of New Zealand. In Tahiti the stranger was upon arrival solemnly invited to take part in a banquet; friends related by kinship were welcomed in one's home and as soon as possible the feast was arranged. Gifts were exchanged, and to withhold from the guest anything which he might request was regarded as a disgrace.

The factors which promote hospitality are: fear of the stranger, who appears as the bearer of magical powers and mystical attributes; explicitly religious commands; the need of foreign articles of trade; the desire to achieve importance by the display of one's own wealth and the desire to hear and exchange news. Especially in higher cultures hospitality is interspersed with magical and mystical elements, which make necessary special formalities and ceremonies; whoever observes these definite forms is sure of protection. Among the pre-Islamic Arabs the stranger in search of aid insinuates himself into the community of his host by touching something which is holy to the latter; for example, he may take his host's child by the hand or may hang his own bucket on the tent rope next to that of his host. Odysseus in the house of his host, the Phaeacian king Alcinous, sat in the ashes on the hearth. Joint celebrations with the guest operate as a communion and involve the obligations of artificial kinship. Women frequently serve as the agents for the reception of the guest, as is illustrated by the story of Odysseus and Nausicaa and by the legends of Tahiti.

In antiquity the symbol of hospitality con-

sisted of a colored tablet of metal or wood which was broken into two pieces, one of which was given to each of the persons bound by hospitality. The pieces were bequeathed by the families on both sides to their descendants and served to identify visitors. Among the Greeks and Romans hospitality was given religious sanction; Zeus Xenios and Jupiter Hospitalis watched over the security of strangers. In Homeric times every guest was bathed, clothed, entertained and not until several days had elapsed—at least not until after the meal was completed—was he questioned as to his name and origin; guest gifts were then exchanged. The hospitality of the Christian Middle Ages assumed a religious character. After the Frankish capitularies of the years 802-03 the right of hospitality, which extended even to the enemy, included shelter, hearth and water and usually food for three days. In the Middle Ages the monasteries performed the functions of hospitality by establishing hospices, especially at dangerous mountain passes.

The reciprocal exchange of gifts between guest and host represents an early form of trade. In view of the lawlessness of the stranger among primitive peoples intertribal business was first confined to personal or family contact between the members of different communities. A native who insulted a guest would by doing so have disgraced his own community and discouraged the stranger seeking trade; it was primarily on this account that the violation of the law of hospitality was regarded as a serious crime.

Hospitality reflects primitive and archaic legal concepts; it represents a kind of guaranty of reciprocity—one protects the stranger in order to be protected from him. The stranger is a public enemy in the sense that he is one who may cause evil; the lawlessness of the stranger was therefore the cement of political organization. The Latin *hostis* originally signified enemy in the sense of stranger; only later did the word *peregrinus* arise for this connotation. The Greek *xenos*, derived as it is from the root *ska* meaning to harm, may have had the same original meaning as *hostis*. In Greece, where until the end of the sixth century permission to enter into the national territory was inherent in the compact of hospitality, the law concerning the rights of aliens changed with the development of more secure forms of government. According to Herodotus (1: 22) the Milesians concluded a pact of hospitality with Alyattes of Lydia which granted to Alyattes the right of access to Milesian territory and included the possibility of a military alliance; this combi-

nation of *xenia* and *symmachia* is the oldest known form of Greek political agreement. In Roman international law states with which no special compact existed did not have the right to send delegates to the government in Rome without previous negotiations. In Tahiti also hospitality assumed a political function; in the eighteenth century the members of the secret society of the Arioi were bound by an active hospitality which went beyond the familiar traditional obligation, for personal acquaintance or the lack of it played no role. The claim to hospitality on the part of the Arioi extended to the chief, but while the Arioi left the possessions of their noble friends inviolate they recklessly despoiled the fields of subchiefs who did not belong to the society. Hospitality carried similar guaranties in Greece; the hospitality of Pericles, for example, to King Archidamus of Sparta guaranteed the sparing of the landed property of the former in the event of a Spartan invasion; this was not sufficient, however, to prevent the Peloponnesian War.

When toward the end of the sixth century the domain of peace was extended in Greece through increased traffic, the cities guaranteed to their citizens by means of *symbola*, or covenants, mutual protection and equality before the law. Diplomatic representation abroad originated for the protection of these interests; distinguished citizens of foreign states were chosen as public guests, who served as proxeni to those who had no guests. Thus public hospitality grew out of the private, for the proxeni were preferably chosen from among men who had already dispensed distinguished hospitality. The proxeni also exercised control over aliens; in Sparta this control was very strict and the proxeni could expel undesirable aliens from the state. States attempted to win over the proxeni of a foreign state; Sparta, for example, in this way drew into its political sphere of influence members of the foreign nobility. Foreigners were admitted to Rome on the basis of friendship covenants or by a magistrate's decree. The city granted free quarters to the guests. The representatives of allied communities were accommodated in the city; those not allied were lodged outside, for the *hostis* might not set foot in the city itself. The welfare of strangers was the duty of the quaestor; he attended to housing, provisioning and guest gifts and in the event of the guest's death to burial. Provision for strangers followed conventional regulations prescribed for every occasion by the Senate.

The germ of the decay of hospitality is inherent in the institution itself, in that it inevitably extends frontiers and the domain of peace and promotes trade; as a result there arise public legal principles, which go beyond the personal and the familiar and take the place of hospitality. The guest house is replaced by the inn, the *xenos* and proxenus by the consular officials of the modern state, the symbol by commercial and legal papers.

The hospitality of modern societies has little in common with the old. Primitive hospitality was addressed to the public enemy; in the modern world the distinction between friend and enemy in the political sense is irrelevant. The old hospitality was a social or religious obligation; that of modern times rests with the discretion of the individual. The old hospitality was an integral part of the culture, often a junction of law, custom, religion and trade; that of modern times is incidental and casts little light on cultural life.

HOSPITALS AND SANATORIA. Hospitals have been coexistent with man's settlement in large aggregations; their rise, decay and recrudescence reflect the development of man's culture, social ideals, religious spirit and scientific achievement. As early medicine was sacerdotal, the first organized institutions for the care of the sick were established in connection with temples; in Greece temples of Aesculapius were estab-

lished at Cos, Cnidus, Rhodes and Epidaurus. In time a differentiation among the priests of these temples took place and some of them became concerned exclusively with medical ministrations. Schools were organized and the asclepiades became full fledged physicians whose armamentarium consisted not only of herbs and drugs, poultices, fomentations, massage, baths and gymnasia but also of instruments for the performance of such surgical operations as trepanation. As early as the end of the sixth century B.C. in Greece a special tax was levied to provide for the maintenance of the *demosios iatros*, or communal physician, who attended patients at a place known as the *iatreion*, which with the growth of cities became the community hospital as well as the city dispensary. According to Galen many cities provided physicians with large, light and airy buildings in the fifth century B.C. and the private physician's *iatreion* corresponded to a modern private sanatorium. Some of the numerous helpers in these institutions were medical students, many of whom were recruited from the slaves. In Rome the large landowners established *valetudinaria* on their estates for the care of their sick slaves by the *servi medici*, to which members of the landlords' families would also resort.

The Grecian *xenodochion*, which was an asylum for travelers, gave its name to and served as a model for the early Christian institutions which were founded by St. Basil in Caesarea between 370 and 379 A.D. The emperor Julian built hospitals in Constantinople, where several were subsequently established by St. Chrysostom. Among the institutions built by the emperor Justinian were open air hospitals arranged in a manner similar to those of the ancient Greek temples. With the spread of Christianity hospitals functioned as hospices or shelters for the accommodation of pilgrims, the poor and the lame as well as for the sick, who received little scientific medical attention in these institutions. Helena, the mother of the emperor Constantine, and the Roman matrons Marcella, Paula and Fabiola gave large sums for the building and maintenance of such asylums. In 542 King Childebert founded the Domus Dei at Lyons, and about a century and a half later the Hôtel Dieu of Paris was built. The responsibility for the administration of the hospitals which were heavily endowed by Charlemagne in the various parts of his domain became a matter of considerable importance to the church and in time was entrusted to the monastic orders. The care

of the sick then became for many centuries the exclusive prerogative of the monks and nuns, and lay physicians almost disappeared. The crusades led to the establishment of military monastic fraternities, the most important of which was that of the Knights of St. John of Jerusalem; this group built many hospitals along the line of communication between the West and the Holy Land. The spread of leprosy, plague and syphilis led to the establishment of lazarettos and to the organization of port hospitals where travelers from infected regions were kept for forty days before being allowed to proceed.

The heritage of Greek medicine was perpetuated and brought back to Europe by the Arabs, who established hospitals and medical schools at Bagdad, Damascus, Alexandria and other cities and whose hospitals and school of medicine at Cordova toward the close of the eighth century stimulated the revival of interest in Greek medical classics. It was not until the thirteenth century, however, that medical schools were founded as departments of universities. Although public dissection was occasionally practised, as at Bologna and Montpellier, the teaching was preeminently didactic, with little if any clinical instruction. The hospitals remained under the direction of the monks, although the Lateran Council of 1130 had forbidden monks and priests to practise medicine, particularly surgery, and Pope Innocent III had issued an anathema against it in 1215. In an attempt to extend the influence of the Holy See the latter encouraged the building of hundreds of hospitals modeled after the Hospital of the Holy Ghost at Montpellier.

After the Reformation, when the property of the monasteries was confiscated by the Protestant monarchs, the *spytals*, or hospitals, were closed, to the distress of the homeless and the crippled who had found asylum in them. During this period the hospitals of the Italian states were probably the best in Europe; the hospital of Milan accommodated two thousand patients and in Florence the organization of the hospital was under the care of resident and visiting physicians and provided an out-patient department to serve the poor of the city. In England physicians were for a considerable period opposed to the organization of hospitals, regarding them as competitors for their private practise. The hospitals of England, which had fallen into an extreme state of decadence, were closed by Henry VIII. During his reign, however, St. Bartholomew's and St. Thomas' hospitals received new charters.

There were hospitals in Mexico prior to the coming of the European conquerors; the first hospital established by the latter was built by Cortez in Mexico city in 1524 and the second was that at Santa Fe, which was founded in 1531. A law passed in 1541 ordered that hospitals be founded in all Spanish and Indian towns. About the middle of the seventeenth century the Hôtel Dieu of Quebec and of Montreal and in 1693 the General Hospital of Quebec were erected. The first charter for a hospital in the American colonies was obtained by the Pennsylvania General Hospital in 1751; two decades later New York obtained the charter for the present New York Hospital. Bellevue Hospital, the oldest municipal hospital in New York City, had its beginning in 1736 in a "Publick Workhouse and House of Correction," of which one small section was set apart for hospital purposes. In 1791 the New York Dispensary was opened for the charitable treatment of patients suffering from chronic disease who were financially unable to pay for resident hospital care.

With the exception of their development in ancient Rome, military hospitals are comparatively recent. Concern for the health of armed forces and for the wounded in battle developed with the growth of the modern state and the substitution of national armies for hired mercenaries. From the time of Aurelian (270-75) free medical treatment of the soldier had become a recognized principle. While warfare was limited to the peninsula it was possible to billet the wounded in private houses or to treat them in tents behind the battle lines, in the private hospitals maintained by Roman landlords or in the retreats, at times fortified, organized for the purpose. When, however, the troops were sent into distant lands and when they occupied foreign territory, the camp included a field hospital for each two cohorts. Byzantium preserved some of Rome's military hygiene, but in the Middle Ages the mode of warfare between feudal lords made such organization impossible. Military hospitals were built by the crusaders to take care of the maimed, the blind and the crippled who drifted back from the East, and during the Spanish-Moorish wars there was some recognition of the need of a military medical organization. Queen Isabella is credited by Hernando del Pulgar with having maintained ambulances and field hospital service at her own expense. One of the first stationary military hospitals was built toward the close of the sixteenth century at Pamplona. In England military hospitals were first estab-

lished during the reign of Henry VIII. In the latter half of the seventeenth century much was written concerning the sad plight of the sick and wounded soldier by the Pole Janus Abrahamus à Gehema. It was in Prussia that military medicine and hospitalization were first developed; other countries, including Austria, Russia, France and the United States, soon followed.

The low estate of the medicine of the period, coupled with the dichotomy between the physician and the surgeon, who often served also as barber and bath keeper; the overcrowding of patients in hospitals; the lack of proper ventilation and of appreciation of the spread of infections, all contributed to the ill repute of the hospitals both civil and military. The impetus for the reorganization and modernization of hospitals came toward the end of the eighteenth century, largely as a result of John Howard's exposé of the offensive conditions prevailing in hospitals, lazarettos and prisons. Much was also done to reform conditions in hospitals by the improvement of nursing standards through the work of Pastor Fliedner and his wife in Germany and of Florence Nightingale in England. Modern principles governing the construction of military hospitals were first formulated by a committee of the French Academy of Sciences in a report published in 1788. Although the organization of hospitals as adjuncts to medical schools in England likewise stimulated improvements, it has been only during the last fifty or sixty years, since the birth of bacteriology and the introduction of aseptic surgery, that the modern hospital movement has been under way.

The complicated organization of modern life and the refinements of medical and surgical diagnosis and treatment have led to the development of modern hospitals for the care of the sick. The extent and character of hospital provision vary from country to country, depending on tradition, wealth, social outlook and political structure. For many countries the complete data concerning hospitalization are difficult to obtain, for it has not been customary to collect such statistical information or to record it systematically or inclusively. The figures which are presented in the following table have been obtained largely from the *International Health Yearbook* of the Health Organization of the League of Nations. England and Wales appear to be most adequately provided with hospital facilities; in these countries there is an average of between nine and ten beds for every one thousand persons, including general and special hospitals, voluntary and what

HOSPITAL FACILITIES BY COUNTRIES*

| COUNTRY | YEAR | HOSPITALS | BEDS | BEDS PER 10,000 POPULATION |

* Data on custodial institutions are not included.

† 7734 of which are small isolation hospitals with 70,462 beds.

until recently have been known as poor law institutions, fever hospitals, those for the tuberculous and the mentally alienated, and sanatoria and convalescent homes. Other countries relatively well supplied with hospitals are, in the following order: Scotland, Germany, Switzerland, Denmark, Sweden, the United States, Canada, Norway, Austria, Australia, the Netherlands and Northern Ireland. All other countries fall sharply below the ratios of these countries. In some countries, such as Australia, Poland, Hungary and Bulgaria, the preponderance of existing facilities is in the general hospitals; in other countries, as in the United States and Sweden, the great bulk of hospital facilities is devoted to special purposes. In the majority of countries the number of beds in general hospitals is about the same as in the special hospitals. The existing differences are conditioned by the extent of urbanization, the development of medical research and teaching as well as the degree of the development of specialism; and above all social policy, for the special hospitals are as a rule hospitals for the treatment of prolonged and linger-

ing diseases and are in the majority of instances built and maintained by the state or its political subdivisions. Among the special hospitals the mental and the tuberculous hospitals claim the major share of beds. In the United States the number of beds in hospitals for nervous and mental diseases outstrips that in the general hospitals; in 1930 the general hospitals had 371,609 beds and the mental hospitals 437,919. In the same year the tuberculosis hospitals and sanatoria reported a total of 65,940 beds, or less than a seventh of the capacity of the mental hospitals. With the possible exception of Sweden, the number of beds reserved in each country for the mentally alienated exceeds that for any other single type of disease.

Outside of Great Britain, the United States and Canada the voluntary hospital, built by philanthropy and governed by a lay board of trustees, is practically unknown. Such voluntary hospitals as exist in Europe are for the most part church or Red Cross hospitals or those established in comparatively recent years by industrial enterprises for the benefit of their employees or by insurance societies for their beneficiaries. The overwhelming majority of hospitals are maintained by tax funds, state or local, or both. Of all the countries of continental Europe Holland has the largest proportion of private hospitals; in that country the care of the tuberculous as well as of the insane devolves wholly upon voluntary religious institutions. Neither in Holland nor in the English speaking countries have the voluntary hospitals been able to meet community needs. In Great Britain, the traditional home of the voluntary hospital, the beds in tax rate hospitals outnumber those in voluntary hospitals by a ratio of five to one, and the financial difficulties experienced by the voluntary hospitals during the last ten years may call for a further extension of rate hospitals. In the United States despite the vast wealth donated for hospital purposes by individuals and philanthropic foundations the government owned hospital beds in 1930, including federal, state, county and city hospitals, totaled 619,726, while the privately owned hospitals, including church, fraternal, industrial, proprietary and non-sectarian charity hospitals, comprised 336,143 beds. With the proposed further extension of federal hospitalization of World War veterans, by which hospital care will be provided without charge to the 4,000,000 men who were enrolled in the American armed forces during the war, the number of beds in government hospitals will

greatly increase. In addition to military, naval and veterans' hospitals the United States government maintains under the direction of the United States Public Health Service hospital facilities in 157 ports for the benefit of American merchant seamen, members of the coast guard and steamboat inspectors.

Mutual benevolent or insurance associations and trade unions have only occasionally found it necessary or possible to organize their own hospitals. Although the last two decades have witnessed a wide adoption of medical service in industry, large industries have not established hospitals except in connection with mills, factories or mines located far from existing hospital centers. In 1930 there were in the United States only 146 industrial hospitals, with a total capacity of approximately 7000 beds. Some of these hospitals are operated by employees' mutual benefit associations through specially formed hospital benefit associations. Fraternal hospitals in the United States number only seventy-seven, with a capacity of about 5600 beds. Labor unions do not maintain hospitals either in the United States or in Great Britain except for a few tuberculosis sanatoria and the Manor House Orthopedic Hospital at Golders Green, London, which is maintained by funds furnished by members of the trades unions through a contributory scheme. Working men's insurance funds of various European countries maintain their own hospitals and sanatoria only in exceptional instances, for they find it more economical to utilize the existing hospital facilities, which depend for their maintenance to a large degree on the payments of the funds. In Germany in 1930 eight insurance organizations with a total membership of 1,356,000 maintained jointly nine hospitals with a bed capacity of 1069. Three funds, supported by 761,000 members, owned jointly four lung tuberculosis sanatoria, accommodating 411 patients at one time; 104 funds, covering a membership of almost 5,000,000, maintained 123 convalescent homes with 6712 beds.

The only country in the world where medical service has been completely socialized is Soviet Russia. Even under the old regime there was a state medical service in the rural districts, or *zemstvos*, and the hospitals, such as there were, were all tax maintained institutions. Little progress seems to have been made in the hospital field during the first decade of the Soviet regime, but the five-year economic plan projects an ambitious program for the development of public

health and hospital services. The present law provides for insurance against the contingencies of sickness, toward which all gainfully employed persons contribute; the hospitals, however, particularly in the remote rural areas, have been unable to meet the demands made upon them. According to the official program of the Russian Socialist Federative Soviet Republic it is to have by 1933 for every 10,000 population seventy-six beds in general hospitals, thirteen beds in contagious disease hospitals, eight beds in maternity hospitals and between three and four beds in psychiatric hospitals. The execution of such a vast plan of hospitalization calls not only for an enormous outlay of capital but for a large corps of physicians, technicians of various kinds and qualified nurses. At the present time there are about 40,000 physicians for a population of 160,000,000. According to the testimony of members of the party of British physicians and scientists who recently visited the hospitals and medical institutions of Soviet Russia, "... the large hospitals in Leningrad and Moscow appeared to be staffed as adequately as our own, and many medical men were working in laboratories, so that it must be conjectured that in rural districts there was great scarcity. Of the new medical students, 40 percent were peasants from the collective farms" ("*Soviet Medicine and Hygiene*" in *British Medical Journal*, December 5, 1931, p. 1043-44).

The financial investment in hospitals exceeds that in many important national industries. C. Rufus Rorem estimated in 1928 that the investment represented by the hospitals of the United States amounts to about \$3,000,000,000 and that the total annual cost of hospital maintenance in this country amounts annually to about \$900,000,000. In other countries the cost of hospital maintenance is lower than in the United States in proportion to the lower prevailing commodity prices and the lower scale of wages and because of gratuitous labor which the hospitals obtain through the religious sisterhoods and through the aid of convalescent patients. In each country the cost of hospital maintenance varies, depending upon the location of the hospital and the prevailing level of prices and wages as well as on the amount of service and the quantity of materials supplied. As a rule the cost of maintenance of the Catholic hospitals is lower than that of others because of the free services rendered by the religious sisters; certain types of special hospitals, such as those for the care of the insane and the tuberculous, have a lower per capita cost per

day than hospitals for acute diseases. Hospitals performing only routine services are administered less expensively than are university hospitals, where teaching and research add to the cost of maintenance. Construction costs also vary with the purpose and location of the institution. The modern compact skyscraper hospitals, built to utilize all possible space and to conserve energy, are less expensive to administer than the older type of hospitals which consist of a series of detached buildings or pavilions. An investigation by Edward F. Stevens revealed the fact that even in the modern compactly built hospital only a little over one fifth of the gross floor space is devoted to patients' rooms and wards. A similar study made in Germany indicates that considerably more space is given to patients' quarters abroad than in American hospitals. While the construction costs of American hospitals vary from place to place, they may be estimated to be about \$7500 a bed; the construction costs in Germany are about one third of this amount.

The question of whether smaller hospital units, scattered in strategic points throughout the community, are more desirable than enormous skyscraper hospitals has not as yet been definitely settled. Many students of hospital organization and management are of the opinion that a hospital of about 500 beds constitutes the optimum unit from the point of view of efficient economic and medical administration. The present tendency seems to be in the direction of larger units built along a vertical axis. On the continent of Europe, where the pavilion type still prevails, the hospitals are composed of an aggregation of self-contained units, one for each specialty, occupying many acres of ground; and their total capacity is generally larger than that of hospitals in the United States or Great Britain. With the growth of cities and the increase in real estate values the tendency everywhere is toward greater compactness in building; and the experience in the United States has demonstrated not only that it is more economical to administer compactly built hospitals but that there is no danger of the spread of infection if the institutions are properly administered.

The work of a hospital is measured not only by the number of patients it accommodates in its wards and private and semiprivate rooms but also by the service rendered to ambulatory patients. The number of these patients is many times larger than the number of resident patients, particularly in countries having no social insur-

ance. In the United States in 1929 about 6,650,000 persons resorted to dispensaries; the number of visits exceeded 19,000,000. Dispensary or outpatient service has taken an important place in the community provision for the care of those who cannot afford the services of specialists or the cost of such diagnostic or therapeutic measures as various laboratory procedures, X-ray service, diathermy and the like. In European countries dispensaries are likewise patronized heavily despite the health insurance because of the tradition established by the university hospital ambulatories, where the work has been and continues to be carried on by the teaching staff (see CLINICS AND DISPENSARIES).

An indispensable complement to the hospital service is the convalescent home, which is usually located outside of the city limits and devoted to restorative work. The essential features of proper convalescent care, such as rest, diversion and proper diet, cannot be obtained by the majority of city dwellers in their own homes. Furthermore with the increasing pressure on hospital facilities, created as a result of the attractiveness of the modern hospitals and a realization on the part of the public that the best care is obtainable in institutions devoted to the purpose, the average duration of a patient's stay in a hospital has been considerably shortened; patients are often requested to leave the hospital long before they are able to resume their ordinary duties. Institutional convalescent care is a community economy, for it provides care at half the cost of hospital care and it prevents breakdowns, thereby diminishing the number of repeaters in hospitals. The cost of construction of a convalescent home is less than half of that of a hospital. Just as dispensaries are being organized by the insurance funds of Europe to provide properly supervised and adequate care for the ambulatory sick, so is convalescent care becoming more popular as a result of the appreciation of its value in preventive medicine.

Similar considerations have led to the establishment of sanatoria throughout the world. These, usually located in attractive urban sections or in the country, were first designed particularly for the well to do; but of late they have become available to other classes of society, particularly the sanatoria for the treatment of chronic diseases, such as tuberculosis, intestinal and metabolic diseases and mild mental disorders, all of which require a special regimen. Spas may also be mentioned in this category. The value of certain mineral springs for bathing

and drinking purposes was known in antiquity. Their use in Europe and in other parts of the world has been continued uninterruptedly and constitutes an important addendum to the medical resources of the world. Sanatoria and hospitals are maintained in Europe by sickness insurance funds and by various municipalities as well as by armies and navies. In Soviet Russia extensive use of spas and sanatoria is part of the state program of health service.

The hospital is an indispensable school and workshop for the physician. It is in the hospital that he is taught his profession; it is here that he can carry on research as well as practise his profession scientifically. In many states of the United States and in many foreign countries license to practise medicine is given to a medical graduate only after he has completed satisfactorily a period of internship in a hospital recognized for the purpose. The medical graduate is conscious of the intricate character of the modern practise of medicine and its dependence on many ancillary facilities, and he is at a loss when he finds himself without a hospital connection after the completion of his period of internship. Neither in the European countries nor in the United States has it been possible to provide every practising physician with hospital facilities. This handicaps the medical man not only in his development as a physician but also in the practise of his profession. If he has no hospital appointment he cannot perform any surgery except by resorting to a proprietary hospital or sanatorium operated for profit, where the standards of service and the character of the adjuvants may not always be of the highest order.

Outside of municipal or voluntary hospitals, which are associated with medical schools and where the positions are held by university teachers, medical appointments are made either by the appropriate city authorities, as in the case of municipal hospitals; by boards of trustees, as in voluntary hospitals; or by ecclesiastical boards, as in church hospitals. Favoritism in appointments is guarded against in many instances by regulations whereby appointments to the medical staff are made by the appointing authorities on the recommendation of the medical board of the hospital.

The rules of the majority of hospitals provide that physicians shall not charge fees for their professional services to patients in the public wards. Fees are, however, collected from patients in private and semiprivate rooms. In municipal hospitals, where there are no accom-

modations for private patients, the visiting physicians and surgeons do not derive any direct economic benefit from these associations. It is necessary therefore for them to have additional hospital connections with voluntary hospitals, and this sharpens the competition for association with voluntary hospitals. In Great Britain and in some other countries the hospitals have no accommodation for private patients, who are compelled to patronize nursing homes, proprietary institutions maintained for profit. In the United States in late years such nursing homes or proprietary hospitals have increased in number, even in cities where abundant hospital facilities exist. There is a twofold reason for this development. The American Medical Association and the American College of Surgeons have developed minimum standards with which all hospitals must comply in order to be rated as approved hospitals. Among the requirements are proper recording of cases, the study by a competent pathologist of all the tissues and organs removed from patients at operations and conferences and stated meetings at which untoward developments must be explained by the physicians and surgeons. Some practitioners object to these safeguards as control over their professional performance. The second factor has been the policy on the part of hospitals to restrict their staffs to a few selected men who work as a team and who are responsible for all the activities within the hospital; this makes it impossible for many medical men to obtain hospital affiliations and leads them to have recourse to the proprietary institutions.

In addition to the caliber of the medical profession the efficiency of a hospital performance depends on the amount and quality of the nursing service. When comparisons are made between hospitals, the number of beds alone is not a sufficient indication of the available service; this must be expressed or weighted in terms of personnel, particularly nursing personnel, available, for infections and other untoward conditions develop in hospitals in inverse ratio to the number of available nurses. Except for obstetrical services American, Canadian and British hospitals use student nurses in carrying out the hospital routine work to a larger degree than do the hospitals in continental Europe. The ratio of student nurses to trained nurses varies greatly in different countries. While in the medical wards of the Austrian hospitals this ratio is eleven to fourteen and in Belgium and Denmark seventeen to eleven, in Germany nine to twelve and in

Holland thirty-one to eighteen, in England it is as high as twenty-nine to seven, in Canada thirty-one to seven and in the United States thirty-five to eight.

The complicated techniques of modern medicine and modern surgery require elaborate apparatus and laboratory services for diagnostic and therapeutic purposes; as techniques have developed, the costs of hospital maintenance have mounted steadily. In the United States the average daily cost of maintaining a patient, exclusive of interest on capital investment and depreciation charges, is about \$5.00 in a hospital for acute conditions and about \$3.00 in a hospital for the care of patients afflicted with chronic maladies. In Canada and in European countries the costs are appreciably lower. The distribution of the maintenance expenditures in general hospitals is much the same everywhere. In a selected group of twenty-one typical American hospitals, which includes the ordinary voluntary hospital as well as university and municipal hospitals, the major expenditures were: salaries and wages, 46.4 percent; food, ice and water, 23.4 percent; medical and surgical supplies and equipment, 8 percent; fuel, light and power, 6.7 percent.

The rates charged ward patients are usually below actual costs, and a large proportion of these patients pay only part of the rate or none of it. Private hospital room rates are similar to or below hotel rates. The charges for laboratory, X-ray and other services become considerable in the aggregate, particularly if the disease is protracted. Such costs weigh heavily upon those who have low incomes and for this reason many of the voluntary hospitals are establishing semi-private services, which offer accommodations in rooms where provision is made for several patients and where the rates for maintenance and for auxiliary services are below those prevailing in the private rooms. In some instances the hospitals limit the maximum which physicians and surgeons may charge patients for their professional services. In the United States as well as in other countries it is the middle class which finds the onus of hospital costs a particularly serious drain on its resources. The wage earning population must have recourse largely to the facilities of public or charity wards, which vary in adequacy in different communities. All the countries of Europe have insurance against the contingency of illness, and the recent tendency is to provide medical care in hospitals and dispensaries instead of in the homes of patients or in the offices of physicians. In some countries,

notably in Germany and Austria, the contributions made to the hospitals by the insurance funds constitute an important item in their finances. In recent years there has been a marked tendency in hospitals all over the world to make the patient bear directly or indirectly an increasingly large part of the hospital costs; entirely free services are reserved for the indigent. The charitable work done by hospitals is no longer measured in terms of the amount of absolutely free care given but by the difference between what the patient pays and the actual costs.

Hospitalization in rural sections of the United States, facilitated by financial assistance from the Commonwealth Fund and the Duke Endowment, has made rapid progress. In England and in the densely populated continental countries, where the distances between provincial towns are not great, the rural hospital problems are not so acute as in the United States. Small cottage hospitals are provided in the sparsely settled sections, and the Red Cross maintains hospitals especially in the remote rural areas of Scandinavian countries as well as in some of the eastern countries.

HOSTOS, EUGENIO MARÍA DE (1839-1903), Latin American publicist, sociologist and educator. Hostos was born in Porto Rico and at the age of thirteen was sent to Spain, where he studied at the universities. His literary activity began in 1863 with the publication of *La peregrinación de Bayoán* (Madrid), a novel written to point out the helplessness and exploitation of the Spanish colonists in the West Indies. For six years he collaborated with such eminent men as Salmerón, Azcárate, Giner de los Ríos, Valera, Martos and Castelar on Spanish reviews and newspapers. He was affiliated with the republicans of Spain in the belief that a republic would accord the colonies their independence in a federal system but left Spain when the Spanish Republic was established (1873-74) and its officials refused Cuba its independence. After a brief residence in New York he visited nearly all the American countries as an apostle of Cuban independence and of a federal union of Cuba,

Porto Rico and the Dominican Republic, which he advocated throughout his life as the wisest political organization for the Antilles. For a number of years he was professor of constitutional law at the University of Santiago in Chile and held the chair of sociology, international law and penal law in the Dominican Republic.

Hostos distinguished himself not only as a revolutionary publicist but also as a sociologist and educator. He tried to found a new morality and sociology and evolved a complete sociological system. He regarded society as an organism which developed according to certain formulated principles and considered that the moral idea would ultimately triumph in accord with natural law. Morality was the basis of order and duty the basis of morality.

Hostos, convinced of the efficacy of the educational work of the government, represents a tendency quite general at the time to admire Protestantism and to attribute to the Catholic tradition the decline of Spanish civilization. He was a constant protagonist of educational reform. In Santo Domingo he was responsible for an educational renaissance. Before his time the schools were poor and few in number; he established a normal school and through his efforts a regular system of educational administration was initiated by the government. He was an intellectual force throughout Latin America and his powerful educational influence, like that of Andrés Bello, was felt in various branches of learning. He was the author of works of literary criticism, political theory, law, pedagogy and sociology. Of his numerous works, comprising more than fifty titles, the following are especially worthy of mention: *Lecciones de derecho constitucional* (Santo Domingo 1887, new ed. Paris 1908); *Reforma de la enseñanza del derecho*, in collaboration with Valentin Letelier and Julio Bañados Espinosa (Santiago, Chile 1889); *Descentralización administrativa* (Santiago, Chile 1890); and *Cartas públicas acerca de Cuba* (Santiago, Chile 1897).

HOTELS. Primitive peoples living in comparative isolation have invariably extended hospitality to the occasional wayfarer, who brought them welcome news and contacts with other communities. As population grew denser and travel more frequent, the force of the earlier law of hospitality diminished and strangers were ex-

pected to pay for their food and lodging. In some communities certain families began to receive all the travelers, a practise to which may be traced one origin of the inn. The earliest development of commercial or public lodging places occurred along the important trade routes or in and near religious centers. Rough caravansaries one day's journey apart were scattered throughout Egypt and Babylonia; in the Persian Empire they frequently gave place to a more substantial type of inn, while similar shelters served the traveler from Europe to China almost until modern times. The Greeks and probably earlier peoples maintained lodging houses for travelers within or near their temples, where the grateful guests left behind gifts according to their means.

The spread of the Roman Empire, based on the unification and pacification of large areas and the construction of post roads, made travel easier and more frequent. Large numbers of traders and provincials were drawn to the metropolis. In Rome itself and in many places throughout Italy they were put up at public inns, which in spite of a rather rigorous state supervision were noted for miserable accommodations and bad reputations. In the vast majority of cases these inns were nothing but bawdy houses and were frequented by gangs of thieves recruited from all races. Nevertheless, throughout the empire the traveler could still find lodgment almost everywhere in temple inns.

In the early Middle Ages traveling in Europe practically ceased. The roads were in general well nigh impassable and infested with bands of brigands. With the revival of commerce, however, with the increasing importance of the fair and the increasing frequency of religious pilgrimages the problem of lodgment for the traveler again became important. Traveling remained for long extremely dangerous and it was essential that all wayfarers move in groups and arrange to get shelter by nightfall. As in earlier civilizations, religious organizations were among the most important purveyors of hospitality. Several orders of monks had as their main purpose the harboring of pilgrims. Two classes in particular tended to stop at monasteries: the nobility, who were amiably received because it was through their bounty and protection that the monasteries existed; and the poor, welcomed because of the gospel admonition. The middle class were usually obliged to lodge in another type of establishment.

The inn, which catered to their needs, originated throughout most of Europe in the private

dwelling, where the guest took potluck with the family. He slept in the common hall with the servants, children and other guests. Accommodation for horses or other beasts was quite as important as for the masters and in some inns, especially on the continent, the animals were accommodated in the same room with the guests. In Italy the inns of the Roman Empire had never entirely disappeared, and the old traditions of thieving and rascality seemed concentrated in that country; but throughout Europe the inn was the center for all kinds of mischief.

The merchant or craftsman who was forced to travel did not, however, have to rely entirely on these accommodations. Most of the guilds had their own *Herbergen* in the larger cities, while in the fifteenth and sixteenth centuries, when *compagnonnage* became important, each little village was likely to have one inn frequented almost entirely by the traveling brotherhood. Such inns must often have been centers of Freemasonry. The rise of strong nationalistic states was accompanied by the construction of post roads and the appearance of more regular means of transportation. The carrier wagon, the post-boy and the individual trader with his pack horse were superseded along these new roads by the stage coach in England and the diligence on the continent. A regular post for the carriage of royal mail was established in France early in the seventeenth century, and by the middle of the eighteenth century travel by coach was common for all classes. In England the inn had greatly increased in importance upon the suppression of the monasteries; during the eighteenth century both there and on the continent it gained new prominence as a place where horses were rested or changed and travelers kept overnight. The regularization of travel did much to improve the character of such inns; complaints as to the quality of food or bed were still frequent, but the moral character of the inns was admittedly better and the host more frequently a business man and less often a blackguard.

Closely associated with the inn at all times and in smaller communities often indistinguishable from it has been the tavern. The true tavern offered no lodging but only food and liquor. Where, as in England in the sixteenth century, it was forced to close its doors at the stroke of curfew, nine o'clock, it put its patrons out at the very hour when shelter was most needed. In the growing cities the tavern was an important adjunct to the inn. It became the headquarters for the decayed gentlemen, the soldier of fortune or

the priest looking for a temporary respite from duty. The seventeenth century saw a great development of taverns frequented especially by the aristocracy or men of letters. This was the period of the coffeehouse in England and the beginning of the famous cafés of Paris.

Early in the eighteenth century inns of considerable size were appearing in France especially around Versailles. Here were accommodated visitors to the court, merchants and the crowds of tourists attracted by every court wedding or other display. In 1715 there were probably as many as 120 inns around Versailles and the regular innkeepers were beginning to complain of competition from residents who rented out their extra rooms.

The fashion for travel was thus well developed by the end of the eighteenth century. It received new impetus and new direction from the early nineteenth century interest in nature and scenic beauty. But it was the railroad and the moneyed middle classes thrown up by the commercial and industrial revolutions which produced the modern hotel. The word hotel was adopted, first in France and a little later in England, about the end of the eighteenth century to signify a departure from the customary method of housing guests to something more luxurious and ostentatious. The new hotel had its first great development in Switzerland, the playground of Europe, during the early years of the nineteenth century. The Swiss hotel keepers of the period are said to have originated the idea of the resort hotel. French cooks were imported and every effort was made to attract visitors. The Swiss hotel became what it has remained, an international institution. It was the model for the hotels which were springing up all over Europe. The railroad companies soon saw the advantages of the resort idea; and as posting houses had earlier established themselves at the termini of stage coach routes, so hotels were placed at important railroad stations and junctions. The great international fairs and expositions of the nineteenth century gave a new impetus to hotel building. In 1855 Napoleon III returned from a visit to England to build the mammoth Hôtel du Louvre. Nationalistic sentiment operated too to lead many governments to subsidize the building and operation of hotels in colonial areas. Before the World War German hotels in the Levant, in the Far East and in South America were important centers of commercial penetration and imperialist intrigue.

It is in the United States that the hotel has

developed its most spectacular forms. During colonial times and even later in frontier communities the American inn differed little from its European counterpart. Several conditions peculiar to the United States encouraged the building of especially large and especially ornate hotels. The lack of settled traditions of living led to frequent traveling and the need for hotels. American hotels were built to cater to a growing middle class. Many, such as the famous Tremont House of Boston, frankly appealed to the patronage of the newly rich. Others had rates within the reach of almost everyone. Catering originally to frontier communities, American hotels became the epitome of luxury to the ordinary person. All the silks and gilt of the late nineteenth century found their greatest display in the hotels of the period. Competition between hotels took the form of providing increasing comforts for guests. Electric lights, telephones, private bathrooms, elevators and other conveniences were introduced by enterprising hotel keepers. In large cities as well as in smaller towns hotels became social centers for the general public; favorite places for balls, banquets, political rallies, business transactions and other affairs.

A European hotel of five hundred rooms is considered large. In the United States the average size has constantly increased until a hostelry numbering over a thousand rooms is not unusual. Increase in size has been made possible by the elevator, the use of fireproof materials and other new construction methods and by the discovery that it is possible to standardize economically the various services in which the hotel specializes. Throughout early hotel history the barroom, particularly in the small town hotel, was the most lucrative part of the business. The dining room inevitably ran at a deficit, which the bar more than covered. Nevertheless, many hotels gained their reputations through the excellence of their cuisines. The growth in size of the modern hotel has been accompanied by the taking over of a vast number of subsidiary functions. A modern hotel may run a laundry, an ice cream factory, an upholstery department, an electric power plant, a florist shop and many other auxiliary services.

Modern hotels, particularly in the United States, are of three more or less distinct types: the commercial hotel, the resort hotel and the residential hotel. The commercial hotel caters particularly to the transient guest. The traveling salesman was for long its most important patron. At one time there were over 60,000 traveling salesmen in the United States alone, traveling

typically on expense accounts and offering easy money for the hotels. The commercial importance of adequate hotel facilities was evident to most communities. In Europe it was largely its excellent hotels which made Vienna the rendezvous for commercial transactions throughout the Balkans. In the United States one new town after another felt the necessity of hotel building. In spite of the increasing size of the territory covered by the individual salesman with the use of the automobile and the decreasing part played by the salesman in the marketing process, he is still the principal patron of the typical small town hotel.

The resort hotel, usually operating during only part of the year and catering to a vacationing clientele, at first benefited from the increase of motoring and the construction of new roads. But in recent years, particularly in the United States, the larger resort hotels as well as small town hotels have suffered from the competition of thousands of less pretentious roadside inns and the tourist camps which have sprung up along all the main highways.

One of the most striking developments of recent years is the growth of the residential hotel with a more or less permanent group of guests. Unattached individuals frequently find such hotels the most convenient places in which to live. But increasing numbers of families or at least of couples in the larger cities are making such hotels their homes. Many influences can be seen as contributing to this tendency: increasing rentals, the growing independence of women and the increasing difficulty of securing efficient domestic servants are all important factors. Hotel life in many ways represents an intensified city life. Urban characteristics such as impersonality, freedom from restraint and emancipation of the individual are dominant in a hotel community. It attracts persons seeking novelty and excitement, offering the stimulation of constant social contacts and a variety of leisure time amusements. Home life under such conditions becomes highly artificial, and the effect on children of such an atmosphere might become an important social problem.

The hotel business is no longer merely large scale housekeeping. In the United States it has become one of the group of billion dollar industries, and in several of the European countries it ranks near the top in the list of national industries. In such a country as Switzerland the most important item in the balance of trade may be tourist receipts based on the hotel industry.

Most of the European countries have for some years maintained special bureaus for the encouragement of tourist travel. Since the World War a number of countries, notably France, Austria and Switzerland, have found it necessary to provide subventions or to support the credit of the hotel industry. Switzerland in 1921 created the Société Fiduciaire Suisse pour l'Industrie Hôtelière, a kind of central credit institution with a capital of three million francs, one half of which was supplied by the federal government. In the United States the industry has suffered since the war not so much from decreased patronage as from excess capacity. According to a study sponsored by the American Hotel Association (Hamilton, W. L., *Promoting New Hotels*, New York 1930) the number of hotels in the United States increased from 20,800 in 1920 to 26,800 in 1929—a relative increase of from 100 to 129; the number of rooms increased in the same period relatively from 100 to 147. In 1929 alone new construction involved an expenditure of \$519,000,000.

The hotel industry early adapted itself to corporate forms of organization; Ritz began building his chain of hotels in 1880 and after 1900 a large proportion of the German hotels were run on a chain basis. The same basis of organization has been widely adopted in the United States.

The fact that before 1914 most hotel managers were Swiss, Austrian or German led to a certain similarity of development in methods of hotel management; since the war chauvinistic attitudes have somewhat changed the situation. As early as the last decade of the nineteenth century associations of hotel owners and managers had been organized in many of the European countries. In addition to various promotional and protective activities these associations have undertaken the development of special schools of hotel management. Similar schools are now in existence in the United States.

The organization of hotel personnel represents an unusually difficult problem. The diversified services require a large staff. The number of employees per guest varies from hotel to hotel but in some of the more luxurious it runs to as high as four or five; the average is probably about one employee to every two guests. Hotel employees are engaged in a variety of occupations. In most cases conditions of employment are exceedingly bad. Employees are usually engaged and discharged by department chiefs rather than through a centralized employment bureau. Often when a steward or housekeeper is engaged he is

expected to bring his personnel with him. A few hotels have inaugurated central employment bureaus where an attempt is made to select people qualified for their jobs. Where this has been done it has led inevitably to a degree of job analysis and training. Most of the schools for hotel executives give instruction in methods of modern personnel management, but the use of efficient personnel methods is still decidedly rare.

Many hotel employees "live in." The workers are frequently housed in inferior quarters and have to eat unsavory food. Lately there has been a tendency to have more of them live outside, but this is often unsatisfactory because of the low wages and the extremely long hours.

Hotel wages are notoriously low. The management although pretending in many cases to deprecate the tendency to tip has by its scandalously low wage rates made it necessary for employees to rely on tips to get an adequate living wage. Since tipping is not standardized but dependent on the whim of a patron, it is difficult for the employee to count on a fixed wage. The custom is not only demoralizing, making for discrimination in service, but means from the point of view of the patron that the initial charge is only the beginning of the price he must pay for adequate service. These evils have been recognized by the more progressive hotel managers of all countries, but nothing effective has been done to correct the condition.

The hotel day lasts for eighteen out of the twenty-four hours and some services must be provided during the entire period. This has meant long hours and night shifts for a large part of the hotel force with a consequent lessening of morale and a shiftlessness in execution of tasks. Turnover is high and many hotel workers move constantly from city to city looking for better conditions. Chambermaids, who constitute about 40 percent of the total work force, are particularly poorly paid, have completely unstandardized hours and the poorest living conditions. Very often they receive no tips for their work. As a consequence turnover is high and only the poorest class of workers will consider a job of this sort. In the United States such positions have largely been filled by immigrant or Negro girls.

In no country have unions of hotel employees achieved any marked success. The character of the work militates against effective organization. In the United States the Hotel and Restaurant Employees and Beverage Dispensers International Alliance, affiliated with the American

Federation of Labor, has lost members heavily since prohibition. The waiters were the only group of hotel workers whom it had ever organized at all successfully, and even in their case the ease with which the trade can be taught and the possibility of importing low priced Negro workers in case of strikes have made organization relatively ineffective. The International Union of Hotel and Restaurant Employees, which is affiliated with the International Federation of Trade Unions, claims a membership in 17 countries, not including the United States and Great Britain, of 74,000. Of this number 75 percent are in Germany and Austria, where organization has made some headway in the hotel and allied industries. There are no figures available for the number of hotel workers in the Red International unions in countries outside of Russia. In all cases figures are misleading because of the inclusion in the unions of food, drink and tobacco as well as restaurant and actual hotel employees.

The semipublic nature of the hotel industry has led not only to its regulation in the interests of public health, welfare and morals but to the development of a large body of legal doctrines relating to the duties and liabilities of hotel keepers and innkeepers. The hotel or inn, in contrast to the boarding house or lodging house, is under obligation to receive all unobjectionable persons who offer themselves as guests and are willing to pay, as long as it has rooms available. The existence of social prejudices, however, quite effectively nullifies the legal rule. Probably because of the necessity in earlier times of protecting travelers and preventing collusion between the hotel keeper and robbers most legal systems have placed on the hotel keeper an extraordinary degree of responsibility for the goods of his guests. Under Roman law he was absolutely liable for all damage or loss; up to the end of the nineteenth century this conception prevailed in civil law countries. In England as early as 1574 the famous Coyle's case (8 Coke 63, 1574) laid down the rule that an innkeeper was not liable except for negligence. Although the doctrine was reversed in the early nineteenth century, legislation in most countries is now tending toward this position. The rapid development of the industry and the great increase in travel have rendered the older law burdensome and unnecessary, and hotel keepers have brought pressure upon governments for legislative limitation of their liability. In the United States, where the rule in Coyle's case

had not been followed by the courts, statutory limitation began in 1855 when New York and Pennsylvania passed acts permitting a hotel keeper who provided a safe to protect himself from liability for property not deposited with him by giving proper notice. England gave statutory recognition to the limitation of liability in 1863; France followed in 1899 and 1911 with laws limiting liability for damages to 1000 francs; Germany passed similar legislation in 1900, Belgium in 1907 and Switzerland in 1911. In Italy the old Roman law doctrine still holds. In the United States rules vary in the different jurisdictions, but the trend is clearly toward limitation of liability to cases of negligence.

HOTMAN, FRANÇOIS (1524-90), French jurist. Hotman first taught Roman law in Paris. Attaching himself to the party of religious reform he became one of Calvin's secretaries. From time to time he played an active but doubtful role as a political agent. In the course

of his later wandering and unhappy life he taught at Lausanne, Strasbourg, Valence, Bourges and Geneva; he died in poverty in Basel.

As a jurist Hotman, who belonged to the humanist school of Alciati and Cujas, has a high place. His *Commentarii in xxv Ciceronis nobiliores orationes* (Paris 1554, 2nd ed. Basel 1594) is still a valuable contribution to the textual study and legal interpretation of its subject. His *Commentatio tripartita ad libros feudorum* (Lyons 1573, 2nd ed. Cologne 1574) first emphasized the Teutonic origin of feudalism; Hotman appealed to the surviving customs and original sources of feudalism rather than to the codification embodied in the *libri feudorum*. His *L'anti-Tribonian* (written c. 1567, first printed Paris 1603), perhaps his most celebrated legal work, attacked the absorption of his time in the antiquities of Roman jurisprudence. He saw that too great a contrast existed between the world of sixteenth century France and that of Justinian, between the French customary law and the Digest. He maintained that Roman law was too peculiarly a product of Roman social conditions to take the place of equity and natural reason, and he regarded the codification of Justinian as a collection of anachronisms and meaningless fragments which would have been forgotten had it not been adopted by the ruling caste and been used by the papacy in the formation of the canon law, which he no less despised. *L'anti-Tribonian* is in effect an appeal from historical jurisprudence in the Roman tradition to the judgment of men formed in Hotman's school of abstract justice, customary law and knowledge of the Scriptures. It had considerable influence and has its place in the history of the movements which later led to codification.

Hotman's fame as a political theorist is due to his *Franco-Gallia* (Geneva 1573; French translation Cologne 1574; tr. by Robert Molesworth, London 1711), which earned for him a European reputation in a few months. It is an attempt to define *La forme de la police de nostre chose publique* and provides a rapid survey of the development of French institutions. His thesis is in brief that the amalgamation of the Gauls and Franks produced a new creation, *Franco-Gallia*. The characteristics of this new regime, which prevailed until the growth of centralized monarchy destroyed it, were the limited nature of kingship and the existence of representative assemblies. This well defined system was to Hotman a harmony which had been reduced to discord by the encroachments of royal power,

and he aimed at its restoration. In his *Brutum fulmen* (Paris 1585, French translation same year) Hotman took advantage of the excommunication of Henry IV by Sixtus V to launch a sweeping attack on the papacy. This treatise is too negative and destructive, but it contains many of the elements which marked for centuries the Gallican theory of the limitations of papal authority.

HOURS OF LABOR. In the lower stages of civilization, where labor is not yet clearly separated from the entire complex of activities constituting life, it is customary for man to work as long as is necessary for the satisfaction of his elementary needs or the needs of his tribe. Only when work has become regularized and crystallized as a distinct activity does the problem of the hours of labor arise. The separation of work from life in general does not occur simultaneously in all parts of the social system. In this connection it is especially important to distinguish between independent and dependent labor: even in comparatively advanced civilizations independent labor—or what merely appears as such—permits of no easy separation of working from non-working time. In the typical family enterprise of the farmer, handicraftsman or small trader there are obviously no fixed hours of labor; working time is determined by the extent of human endurance, by the requirements of the particular pursuit and by external conditions, such as the weather and hours of daylight. This is not infrequently true also of the quasi-independent producers in highly developed modern society; under the pressure of competition from large scale industry they tend to draw no distinction between the hours of labor and those of rest, regarding the duration of their working time as a purely private matter. This attitude, characteristic of the lower middle class, is still an impor-

tant factor in semi-industrialized countries, where it has enormously impeded the regulation of working time in agriculture and handicrafts, in which independent and dependent labor work side by side. Another typical example of this antiquated attitude is the housewife in working men's families. The idea that her labor hours might also be limited seems to be entirely foreign to a working class housewife; yet her day begins before her husband goes to work and she continues to toil after he returns home.

The problem of working time does not arise in a society based on independent labor nor in one based on slavery; in both the length of the working day is a technical rather than a social question. Only when society has become stratified into classes and when there exist alongside independent and slave labor various forms of dependent and semidependent labor, does the problem acquire a social significance. For wage labor and the labor of serfs on the land of the feudal master the working time measures the degree of dependence of one social class on another as well as the degree of exploitation. In such a system or systems working time is determined by the living conditions of society as a whole—needs, resources available for their satisfaction and similar factors—and by the distribution of power among the social classes.

In an economy with a static technique working time will be lengthened in proportion to density of population and shortened with the increase in the power of the lower strata of society. Other things remaining equal, the progress of technology will tend to diminish the number of working hours. And yet working time does not merely depend upon technical and social progress; it also strongly influences them. When the hours of labor are excessive, the worker is denied the opportunity to become a capable citizen. A democratic regime acquires vitality only through the shortening of working time, which releases millions of people for civic activities. Shorter hours also contribute to social progress in another way: increased leisure at the disposal of employed workers tends to stimulate new wants, leading to an expansion in the demand for consumer goods and to a more intensive operation of the productive system. Technical progress too is necessarily hampered by excessive labor hours; the prevalence of such conditions implies the existence of cheap, easily satisfied labor which employers can exploit without the aid of expensive machines but which is also incompetent to operate complicated machinery. The reduction

of hours acts as a spur to increase efficiency; the employer is forced to rationalize and mechanize his plant and the laborer, no longer worked to the point of exhaustion, is better able to concentrate and to adapt himself to new processes.

The problem of working time is not simply one of shorter hours. Society cannot satisfy its wants except by means of intensive physical and mental effort, and labor must have a definite duration in order to attain the necessary productivity. While too much work means stagnation, too little work means poverty. The fundamental problem is one of finding the appropriate length of working time—appropriate to the particular stage of social development reached and the state of the industrial arts. For each national economy this problem is complicated by international competition and by the differences among the various branches of the system. While an absolutely uniform regulation of the hours of labor is impossible, it is essential that the conditions of labor prevailing among the different groups of workers should be made as nearly similar as possible.

History. The problem of the hours of labor, i.e. the length of the working day, can be traced historically for about one hundred years. Much older is the limitation of working time by alternating days of work with a day of rest, the beginnings of which may be found in antiquity. Thiering's hypothesis that the introduction in Babylon of the seventh day as a day of rest served primarily this purpose is disputed by historians. But the social import of the Hebrew Sabbath (*Shabbattu* in Assyrian means rest) can scarcely be doubted; the severity with which it was insisted that the Sabbath must be a day of complete rest, any infraction of which was strictly forbidden, indicates that the real objective of the old Jewish law was the suspension of work. The Jewish Sabbath eventually developed into the Christian Sunday, which also came to be recognized as a day of rest by the authorities of the Roman Empire under Constantine. Beyond that the temporal power did not concern itself with the observance of Sunday; it was considered a religious institution and the church was strong enough to handle it unaided.

During the Middle Ages working time in urban occupations was limited by the external conditions affecting labor and by religious holidays. Primitive lighting arrangements and the danger of fire inherent in working after sundown definitely limited the length of the handicraftsman's working day. In many cities night work was offi-

cially prohibited. Furthermore nearly every week contained a holiday on which no work was done. In the early Middle Ages scarcely more than 48 hours on the average constituted a week's work; the 8-hour day was the normal working day. Legend attributes to King Alfred the Great the saying: "Eight hours work, eight hours sleep, eight hours play, make a just and healthy day." This condition persisted in the following centuries under the rule of the guilds. Journeymen quarreled with their masters about "blue Mondays" and the number of holidays that should be observed; peasants clashed with the nobility over the distribution of working days between their own land and the land of the lords; but the question of hours of labor seldom arose. In the late Middle Ages, however, working time was lengthened. While the prevailing methods of production remained unaltered, population increased and the economic and social conditions of the mass of the people deteriorated. In England a royal statute [11 Hen. VII, c.22 (1495)] set the working day during the summer from 5 a.m. to 7 or 8 p.m. with 2 hours of rest—an attempt to increase the hours of labor by means of police regulations. Queen Elizabeth decreed a working day from 5 a.m. to 7 or 8 p.m. with 2½ hours of rest [5 Eliz., c. 4 (1563)]. In the fifteenth and sixteenth centuries Sundays and holidays were no longer as piously observed as formerly. During this period also arose the idea of a higher social order in which the working day would last even less than 8 hours. In Thomas More's *Utopia* (1516) the day's work consisted of only 6 hours. The direction of social development, however, was entirely different. At the close of the seventeenth century, according to William Petty, the 10-hour day—12 hours from start to finish, with a rest period of 2 hours—predominated in England.

The growth of capitalism during the second half of the eighteenth century brought an unprecedented lengthening of the working day. The increasing use of expensive machinery; the establishment of large factories whose owners and employees did not work side by side as did the guild masters and their journeymen; the new ideology of the entrepreneurs, who repudiated traditional economic restraints; and improved lighting arrangements, such as gaslight, introduced into factories at the close of the eighteenth century—all these furnished important drives in the direction of longer hours. Little resistance could be expected from the workers; in the absence of protective legislation and organization

for the protection of their status they were forced by mass unemployment to accept work under almost any conditions. Handicraftsmen too were driven to the utmost of their endurance by the fear of succumbing to factory competition. No labor statistics are available for this period, but it is known that about 1800 a working day of 14 hours was customary, one of 16 hours attracted little attention and only a working day of 17 or 18 hours was considered an abuse. Such excessively long hours were worked not only by men but also by women and children, whose labor was used on a particularly large scale in the textile factories. This rapacious exploitation of human labor resulted in a reaction, which followed the turn of the century.

At the beginning of the nineteenth century the situation of the working class in England was at its worst: the working day was prolonged beyond any natural limits, wages were at their lowest and the interests of labor were not protected by law. Shortening of the working day had to proceed hand in hand with an improvement in general working conditions and the development of legal protection of labor. Such improvement depended upon a number of factors—technical progress; recognition of the interest of the state, even if only from a military standpoint, in assuring healthful living conditions to the largest class of the population; the increasing power of organized labor, which as a rule fought first for a shorter working day and later took up with renewed strength the struggle for higher wages; efforts of individual social reformers and the progress of social science. Viewed in its main outlines the history of the hours of labor since the beginning of the nineteenth century may be divided into four periods. The period from 1810 to 1850 witnessed the appearance of pioneer social reformers; the first legislative attempts to limit hours, particularly for women and children; and the emergence of labor unions which demanded shorter hours. In the following period from 1850 to 1880 the growing trade unions intensified their struggle for shorter hours, and the normal working day of 12 to 14 hours was reduced to 9 hours in England and to 10 hours in other industrial countries. During the next period, which extends to the outbreak of the World War, the unions engaged in a struggle for the 8-hour day, the hours of labor were further reduced and the length of the working day became for the first time the subject of systematic research. Finally during the post-war period the 8-hour day has been introduced in the majority

of capitalist countries; while labor has demanded the strengthening of the new regulations concerning hours and fought for a further shortening of the working day, capital has pressed for a relaxation of regulative legislation.

The early attempts to regulate working time consisted of legislative limitation of the hours of labor of women and children, who were less able than men to withstand the harmful effects of excessive work. In 1833 England adopted legislation limiting the working day of minors to 12 hours, and a few years later children under 13 years of age were prohibited from working more than 8 hours. This special legislation marked a departure from the philosophy and practise of *laissez faire*, and it was quickly used as an argument in favor of regulating the working time of adult male workers. The movement for legislative limitation of labor hours for men, which in the modern period dates from the pioneering efforts of Robert Owen, drew its support at first from public spirited bourgeois circles and progressive employers who feared that long hours might cause overproduction and a fall in prices. During the first third of the century labor, downtrodden and unorganized, was scarcely more than the passive object of social reform. Later with the growth of labor organization it began playing a more active part in the struggle for the improvement of its working and living conditions. In the 1840's the Chartist movement had developed a strong agitation for the 10-hour day, which was legally established in 1848. By the middle of the century social and political conditions changed in England and elsewhere. The skilled workers in England then formulated the demand for the 9-hour day, and some of the labor organizations were able to enforce the demand in agreements with the employers. The engineers, for example, secured the 9-hour day in 1872 after a series of strikes, and it was the subject of the majority of labor disputes in the 1870's.

In the United States there was in the first quarter of the century a fairly active movement for the reduction of hours; it was the most insistent demand of the rising labor movement and met with some success. In 1840 the federal government introduced the 10-hour day among its employees and in 1868 the 8-hour day, but private enterprise hesitated to follow the example; the 10-hour day did not become customary until after the Civil War. While for 1840 the average working week was estimated by Mulhall at 69 hours in England, 78 hours in the

United States and France and 83 hours in Germany, by 1880 the 52-hour week—a 9-hour day with 2 hours less on Saturdays—was general in England and the 60-hour week in the United States, Germany, France and Belgium. In Italy the working day usually lasted 12 hours; in Russia it fluctuated between 12 and 13 hours.

By this time organized labor was actively fighting for the 8-hour day. The demand for the legislative limitation of the maximum working day to 8 hours was advanced by the First Socialist International in 1866; in the same year similar action was taken by the National Labor Union in the United States and in 1869 by the Trades Union Congress in England. It became a major issue with the organization of the Second Socialist International in 1889 and the main slogan of the international May Day celebrations. The limitation of the working day, however, was realized not by legislative measures but by collective bargaining with employers. In the United States legislative regulation was scanty and much of it was declared unconstitutional; in addition legislative action among the 48 states was hampered by the employers' claim that reduction of hours would prove disadvantageous in competition with states in which longer hours prevailed. In England there was little legislation directly regulating the hours of labor; the most conspicuous exception was the 8-hours act for miners adopted in 1908. The situation was approximately the same in other countries; in Australia and New Zealand, however, legislative action played a much more important part than elsewhere in regulating the length of the working day among all classes of labor.

After 1890 there was an impressive reduction of hours in the leading industrial countries. In England the movement reached a high point in 1902, when 1,051,983 workers had their weekly working time reduced as against 5524 workers whose working time was increased; the aggregate net decrease amounted to 1,024,868 hours per week. Reductions were much smaller thereafter but reached a new high point in 1909, when 559,674 workers had their weekly working time reduced by approximately 4 hours. As shown in Table I, in the United States the weekly working time in 1913 was less by 4.6 hours than in 1890—a decrease of 8 percent. In manufacturing industries alone the decrease was from 62.2 to 58.8; the hours of unionized occupations declined from 54.4 to 49.2. In Germany organized labor was fairly successful in the struggle for shorter hours so that before the World

War a working day of from 9 to 9½ hours was widespread. But since the working day was regulated mainly by local collective agreements it varied in different districts and occupations according to the strength of labor organizations. These agreements reveal a striking connection between the length of the working day and wages: in districts where the shorter day prevailed the workers earned not only more per hour but more per day than elsewhere. Thus according to statistics for 1905–06 building workers working 11 hours received a daily wage of 3.52 marks and those working 9 hours 5.80 marks; pottery workers working 11 hours received 3.63 marks and those working 9 hours 4.90 marks; metal workers working 10 hours received 3.95 marks and those working 9 hours 4.85 marks. These statistics illustrate the well known connection between lower hours and higher wages; this relation holds not only for the same occupation within one country but also for different occupations and different countries. In Australia and New Zealand, where labor has scored its most impressive gains, the 8-hour day was general.

TABLE I
NORMAL WEEKLY WORKING TIME IN THE
UNITED STATES, 1890–1913

| YEAR | AVERAGE HOURS PER WEEK |
|------|------------------------------|
| 1890 | 58.4 |
| 1895 | 58.1 |
| 1900 | 57.3 |
| 1905 | 55.7 |
| 1909 | 54.9 |
| 1911 | 54.4 |
| 1913 | 53.8 |

Source: Douglas, Paul H., *Real Wages in the United States, 1890–1926* (Boston 1930) p. 208, which covers manufacturing, building trades, coal mining, transportation, unskilled labor and government employees.

In the same period most industrial countries adopted legislation regulating the hours of labor of women and children. In the United States, for example, Massachusetts in 1875 limited the working time of women to 10 hours daily, and in 1895 Illinois limited it to 8; by 1914 the work of children in the majority of states was limited to 8 or 9 hours daily, although in approximately one quarter of the states, particularly in the south, children were allowed to work 10 or more hours. England in 1907 limited the working time of women and young persons under 18 years of age in the laundry industry to 68 hours weekly, allowing time for meals. Thereby legislative regulation of hours for women and minors was ex-

tended to cover virtually all manufacturing industries. The most progressive legislation was adopted by New Zealand and the Australian states. As early as 1873 an 8-hour day for women and young persons was declared for special industries in Victoria and New Zealand. The Factories Act of the latter passed in 1894 influenced the legislation of the Australian states. Within two years all but one of them had limited working time for women and children to 48 hours weekly, with stringent regulation of overtime, which was not to exceed 90 hours yearly. France, dissatisfied with special legislation, adopted in 1900 a maximum of 10 hours daily for all employees. The special legislation limiting the hours of labor of women and children in all cases set a working day shorter than the maximum working day of men workers, but it was considerably longer than the hours of labor of many union groups and of some highly skilled non-union workmen.

Before the World War hours of labor were subject to wide variation with occupation and season. In England the standard working week in 1913 varied in the majority of occupations as follows: shortest period, 46½ to 49½ hours; longest period, 52½ to 56½ hours. In the United States the range was from 44½ to 66½ hours. The hours actually worked showed still wider variations, because employees worked only part time during slack periods and frequently worked overtime when business was good. This should be taken into consideration when international comparisons of working time are made such as those presented in Table II.

Post-War Period. After the World War the 8-hour day was introduced in a majority of the capitalist countries, partly by special legislation and partly by collective agreements between employers and workers. At the International Labor Conference held in Washington in October, 1919, an attempt was made to unify legislative regulation of the hours of labor under international guaranties, but the convention drafted at the conference was not ratified by the leading countries. Nevertheless, the 8-hour day has become so general within the framework of national regulation that it may now be considered the standard working day. And yet no stable balance has been achieved. The employers in the majority of European countries are convinced that the 8-hour day is too short and press for revision of the legislation and collective agreements. The workers, on the other hand, demand even shorter hours of labor, such as a 5-day week of 40 hours.

In the majority of European countries the working week is legally limited to 48 hours, which is also the standard or normal week in the United States. This, however, is simply a basic provision; the standard hours of labor may be shortened by part time work or lengthened by overtime upon agreement of employers and workers, so that the extent to which overtime is utilized is the deciding factor in the length of the working day. The amount of overtime depends not so much upon the extra pay provided for in legislation or agreements as upon the movement of business, which also determines the extent of part time work.

TABLE II
HOURS OF LABOR PER WEEK IN SELECTED COUNTRIES, 1912-14

| COUNTRY | YEAR | PERCENTAGE OF WORKERS WHOSE HOURS PER WEEK WERE | | | | | | |
|-----------------|------|---|----------------------|----|----------------------|----|----------------------|-------------|
| | | 48 AND UNDER | OVER 48 AND UNDER 54 | 54 | OVER 54 AND UNDER 60 | 60 | OVER 60 AND UNDER 66 | 66 AND OVER |
| United States | 1914 | 12 | 13 | 26 | 22 | 21 | 6 | |
| Germany: summer | 1914 | 1 | 11 | 29 | 24 | 31 | 4 | |
| winter | | 32 | 15 | 23 | 15 | 12 | 3 | |
| Italy | 1913 | 6 | 2 | 6 | 3 | 39 | 25 | 19 |
| Netherlands | 1913 | | 10 | | 13 | 35 | 15 | 27 |
| France | 1912 | | 2 | | 2 | 68 | 3 | 25 |

Source: The figures for the United States are census data covering about 7,000,000 workers; they are adapted from *Monthly Labor Review*, vol. xvii (1923) 1306. The figures for Germany are based on collective agreements; they appear in *Die Tarifverträge im Deutschen Reich am Ende des Jahres 1914*, Reichsarbeitsblatt, Sonderheft no. 12 (Berlin 1916) p. 20. The Italian figures covering 981,500 workers appear in Italy, Direzione Generale della Statistica e del Lavoro, *Annuario statistico italiano 1914* (Rome 1915) p. 310. The figures for the Netherlands cover about 441,000 workers in large scale industry; they are taken from Netherlands, Department van Landbouw, Nijverheid en Handel, *Centraal verslag der arbeidsinspectie over 1913* (The Hague 1915) p. 312. The French percentages are based on a classification of hours worked in 284,320 establishments; these appear in France, Ministère du Travail et de la Prévoyance Sociale, Direction du Travail, *Rapports sur l'application des lois réglementant le travail en 1912* (Paris 1914) p. xxxv.

The question of extra pay for overtime in various European countries was investigated in 1928 by the International Labour Office. Overtime rates may be fixed by law or by collective agreements. Poland and Finland had the highest rates: fixed by law—150 percent of the regular pay for the first 2 hours and 200 percent for further overtime (including Sunday). The lowest rates were in Italy—a flat 110 percent for all types of overtime. Rates settled by collective agreements vary from industry to industry. Thus in Great Britain a rate of 150 percent is found in the engineering trades, 125 to 150 percent in the woolen and chemical industries and 125 to 200 percent in the printing trades. The rates range from 115 to 150 percent in Germany, from 130 to 200 percent in France and from 125 to 200 percent in Sweden. In the United States overtime is frequently paid at the normal time rates, but the more general practise is to pay higher rates up to double the normal.

Since the 8-hour day has become the basic one, the statistics of labor hours are concerned not primarily with ascertaining norms but with establishing deviations from them. Moreover a distinction is drawn between hours fixed by law, hours fixed by collective agreement and the actual working time with special reference to part time and overtime. The actual working time, as distinct from the average or normal or the most prevalent working time, can be ascertained only by computing the number of hours actually worked by the individual worker; the data thus obtained are arranged as a frequency distribution indicating how the body of workers is di-

vided into groups according to the length of the working day or working week. Comprehensive international statistics of this nature are as yet not available; efforts to compile them met with obstacles which for the time being have proved insurmountable.

Certain attempts, however, are worthy of being recorded. In 1928 the International Federation of Trade Unions instituted an inquiry through its affiliated national organizations in sixteen countries into the actual working time in the mining, chemical, metal, textile, shoe, printing, woodworking and building industries. The more significant results of this investigation are shown in Table III. Some doubt exists as to the international comparability of those results, since it is not certain that the same methods of inquiry were used in each country. Nor are the combined figures for all countries representative because of the excessive preponderance of the data for Germany.

More reliable are the results of the inquiry into the coal mining industry of Belgium, Czechoslovakia, France, Germany, Great Britain, the Netherlands and Poland in 1925 instituted by the International Labour Office. The inquiry was confined to the typical working time of underground and surface workers, and figures were obtained also for traveling time underground and breaks. While the shift hours in most cases varied from 7.75 to 8.25, the actual weekly working time of underground workers after deducting traveling time underground and breaks was as follows: Great Britain, 37.08 hours; France, 38.50 hours; Belgium, 38 hours;

TABLE III
ACTUAL WORKING TIME IN SELECTED COUNTRIES, OCTOBER 1-6, 1928

| COUNTRY | NUMBER OF ESTABLISHMENTS | NUMBER OF EMPLOYEES (IN 1000) | PERCENTAGE OF PART TIME EMPLOYEES | PERCENTAGE OF FULL TIME EMPLOYEES WHO WORKED | | | | | |
|----------------|--------------------------|-------------------------------|-----------------------------------|--|----------|---------------------|---------------------|---------------------|---------------|
| | | | | LESS THAN 48 HOURS | 48 HOURS | OVER 48 TO 51 HOURS | OVER 51 TO 54 HOURS | OVER 54 TO 60 HOURS | OVER 60 HOURS |

Poland, from 36.77 to 37.80 hours. Surface workers worked from 48 to 60 hours in Germany and about 48 hours in Great Britain and France.

The statistics of individual countries must be drawn upon to supplement the rather meager results of international studies. Turning first to the foremost industrial country of the present time, the United States, we find that American statistics do not distinguish clearly between standard working time and the time actually worked. This accounts in part for the inconsistencies in figures obtained from various sources. The most comprehensive statistics cover the trade unions, which embrace approximately 15 percent of the wage workers, mainly the better paid crafts; but the length of their working day, which is considerably lower than among the unorganized workers, is not characteristic for the working class as a whole. The 1931 figures of the United States Bureau of Labor Statistics, which appear in Table IV, cover about 705,000 organ-

duce the working day to 7 or even to 6 hours, so that the working week contains from 36 to 42 hours. The average working week of trade union members in 1931 consisted of 43.6 hours, which made it about 10 percent shorter than in 1913; in 1890 union labor's normal working week consisted of 54.4 hours.

A working week of 40 hours or less is more widespread among clerical employees than among wageworkers. An investigation of the United States Personnel Classification Board in 1929, which covered 446,626 clerical employees, indicated that 31.3 percent worked less than 40 hours weekly, 20.9 percent from 40 to 44 hours, 27.7 percent from 44 to 45 hours and only 20.1 percent 45 hours or more.

The weekly working time of labor as a whole decreased according to unofficial estimates from an average of 58.4 hours in 1890 to 48.4 hours in 1929. Figures tracing the gradual shortening of the working week and based on material from

ized workers in the principal time work trades. Of them the largest group, limited almost entirely to the building and stone trades, had a working week of 40 hours or less; that is, a 5-day week. The next largest group had a working week of 44 hours, which may be considered standard for organized labor. It is noteworthy that in the agreements concluded by trade unions with the exception of the printing trades the length of the working day has nearly always been placed at 8 hours, even though the working week might vary from 40 to 48 hours, depending on whether it consisted of 5, 5½, 5¾ or 6 days. In the printing trades there is a tendency to re-

different sources are presented in Table v. Statistics compiled through the Census of Manufactures indicate that the number of workers in manufacturing industries working 48 hours or less weekly increased from 11.8 percent in 1914 to 46.1 percent in 1923; those working over 48 and less than 54 hours increased from 13.5 percent to 21.9 percent; and those working 54 hours and over decreased from 74.7 percent to 32 percent. As may be seen from Table vi, the length of the working week varied considerably from trade to trade, the range for manufacturing alone extending from 44.2 hours in the boot and shoe industry to 55 hours in the iron and steel indus-

In other countries on the American continent, except Canada, hours in manufacturing and mining are longer than in the United States. Although specific information is not easily accessible, it may be stated that on the whole conditions are somewhat better in the more industrialized regions. Thus an official investigation which covered 109,520 employed persons in Buenos Aires in 1926 established that for workers of both sexes the average hours are 7.6, for salaried male employers 7.3 and for salaried female employees 7.5. In the smaller cities and in the rural districts of Argentina, however, the working day extends to 10 or more hours. In March, 1930, the government put into effect a law passed in the previous year which made the 8-hour day compulsory for all commercial and industrial enterprises throughout the country. The statute followed the lines laid down in the Washington convention except for the exemption of agriculture and industrial homework. It set a maximum of 7 hours for night work and a maximum of 6 hours for regions with unhealthy climatic conditions.

In Great Britain the average working day in the last pre-war year was about 9 hours. There were only minor reductions in working time between 1915 and 1917; in 1918, 148,000 workers had their working time reduced and the total net decrease for Great Britain amounted to 568,000 hours weekly. In 1919 the average working day was reduced to 8 hours; the reduction affected 6,305,000 workers and the net decrease in weekly working time was 40,651,000 hours. In the following year 570,000 workers benefited by a decrease in working time, the net decrease aggregating 2,114,000 hours weekly. Since then increases in hours of labor have considerably exceeded the decreases, the entire period having been marked by demands on the part of the employers, particularly in mining, for an increase in the length of the working day. In 1926, when the workers were defeated in the coal miners' strike, 934,200 workers had their weekly working time increased, the total net increase amounting to 3,985,000 hours weekly. In 1930 there were aggregate reductions of 873,500 hours weekly affecting 349,000 workers.

According to collective agreements in force at the close of 1930 a normal working week of 47 to 48 hours prevails in Great Britain. In the shipbuilding industry in London 45 hours constitute the working week; in the building trades, 44 to 46.5 hours in the summer and 44 in the winter. The 44-hour week also prevails in some govern-

ment offices. In agriculture the 50-hour week is customary in the summer; in the winter it is reduced by 2 hours. Although the major portion of British labor is organized into unions, figures for the actual working time in particular establishments given in Table VII show considerable deviations from the standard set down in agreements. The lowest average weekly working time was in iron and steel with 50.8 percent of the workers working 44 hours or less; the highest average was in bread baking with 70.4 percent of the workers working 48 hours and over.

In Germany the normal 8-hour day is accompanied by unusual variations in actual working time by branches of industry as well as by localities. These variations are further aggravated by cyclical fluctuations and by conditions peculiar to the German post-war economy. Thus during the rationalization crisis of 1926 part time work increased greatly. In March, 1926, 30 percent of employed trade union members (excluding seasonal occupations) were working part time; the average difference between part time and full time employment amounted to 17 hours weekly, while all employed workers worked on the average not more than 42 hours a week. So high a proportion of part time employment was of course only temporary; the employers believed that the depression would be of short duration and preferred to reduce working time rather

than to discharge superfluous workers. When in 1930 and 1931 the employers were no longer inclined to divide the available work, organized labor attempted to prevent an aggravation of the unusually severe unemployment by advancing the demand for a general reduction of the working week to 40 hours. Although the proposal was regarded as an emergency measure it was intended to pave the way for a permanent reduction of the hours of labor. Whether the 40-hour week should be based on a 7-hour day or should consist of five 8-hour days was left undecided. While part time employment meant in most cases a reduction in the number of days worked, the adoption of the 7-hour day would offer more hope for a permanent reduction in hours.

German statistics on the hours of labor are compiled by two bodies: the Central Statistical Office of the Reich, which collects information as to hours and wages from pay rolls of individual establishments, and the German Federation of Trade Unions, which makes inquiries through its affiliated bodies. While the data obtained by the latter method are neither exhaustive nor strictly accurate they cover a large proportion of workers, supply a fair approximation and are available at more frequent intervals than the official figures. Table VIII based on trade union data includes workers in the chemical, metal, textile, boot and shoe, book printing, wood-

hours for labor as a whole are somewhat longer than those for organized labor and that pronounced differences exist among industries and labor of different qualifications; women workers work consistently fewer hours than men.

In other European countries despite variations due to local conditions the 8-hour day or 48-hour week is recognized as basic in industry. In France a working week of 48 to 50 hours was introduced by law of April 23, 1919. Some industries, such as the textile, operate on five and a half 9-hour days or five 10-hour days. Current statistics are available only for enterprises with more than 100 employees, i.e. for medium and large scale establishments. As shown in Table x,

of 2,586,654 persons employed in 8577 enterprises covered on October 1, 1931, 37.6 percent worked less than 48 hours per week. Belgium, well known for its advanced labor legislation, decreed an 8-hour day (or 48-hour week) by law of June 14, 1921. Under no conditions may the annual maximum of hours set by law be exceeded, but within these limits seasonal adjustments are allowed. Thus by royal order of May 15, 1923, the automobile and bicycle industries were permitted to institute a 9-hour day in the months from December to March provided that the working day be limited to 7 hours in the off season from June to September. Similar adjustments are to be observed in other industries. In Italy since 1927 labor time is regulated by collective agreements between the corporations of employers and employees. As a rule these agreements provide for an 8-hour day but also permit overtime. In 1931 in view of the increase in unemployment the government instructed the ministries and the provincial and

municipal administrations not to allow any overtime work. In Spain a universal 8-hour day was proclaimed after the revolution; the working day of miners was limited to 7 hours by a special decree of August 28, 1931.

The history of labor in Russia since 1917 displays many unique features. Before the World War a working day of 9 to 10 hours was customary in Russia, but after the revolution of March, 1917, the 8-hour day was introduced in virtually all occupations. The new regulation of working time originated with workers' committees of individual establishments or with local soviets, and the managements were forced to accept it, willingly or unwillingly. Later the 8-hour day was sanctioned by the provisional government. The revolution of October, 1917, modified the legal form of the regulations concerning working time, but the length of the working day remained generally unchanged until 1927. In that year the tenth anniversary of the Soviet regime was celebrated by the promulgation of a manifesto reducing the working day to 7 hours. The introduction of shorter hours was due only in part to the consideration that the proletarian revolution must afford the worker a shorter working day than the standard day of capitalist countries. The more important reason was found in the decision to carry on continuous production with three shifts; it was expected that 7-hour shifts would allow sufficient time for the change of shifts, the necessary pause in the operation of machinery, minor repairs and the like. The new regulation became effective in January, 1928, but was only gradually enforced. By October, 1928, only 24 textile establishments, employing a total of 118,600 workers, and 4 others operated on a 7-hour basis. In October, 1929, about 20 percent of all industrial workers enjoyed a 7-hour day; in 1930 it was extended from 43 to 46 percent of the workers and early in 1931 to about 60 percent. The new working arrangement proved, however, impractical and inconvenient. It was bound up with night work on a large scale for women as well as men. Seven hours of uninterrupted work was found to be more fatiguing and harmful than an 8-hour day with a midday rest period. Moreover the three 7-hour shifts did not entirely fill the 24-hour day and night period, which tempted many establishments to change to shifts of 8 hours of uninterrupted work. The workers received in such cases credit for $1\frac{1}{2}$ days or the eighth hour was taken into consideration in the granting of vacations, but in neither case were the injurious effects of an uninterrupted 8-

hour working day done away with; productivity, morale and hygienic conditions were adversely affected.

The failure of uninterrupted work in three 7-hour shifts was one of the main reasons for the decision in August, 1929, to introduce the 5-day week, consisting of 4 days of work and 1 day of rest. Under this plan the division of the year into weeks is eliminated, the factory operates without interruption and the working force is divided into five groups, four of which are always working while the fifth rests. It was anticipated that this would mean a higher degree of utilization of technical equipment as well as the elimination of Sunday, the day of rest favored by religious tradition. On October 1, 1930, 72.9 percent of the industrial and agricultural workers in government enterprises were put on the 5-day week. A reaction, however, was not slow in coming. Enterprises gradually abandoned the "uninterrupted 5-day week" and introduced a working week of 4 days with a common day of rest. In June, 1931, the failure of this scheme was officially recognized and a return to the 6-day week recommended. The 5-day week failed not because of the resistance of the workers to certain minor inconveniences connected with it but because of the technical and economic defects of the system. It resulted in a continuous change of workers at the machines, in the course of which no one seemed able to become accustomed to his place of work and no one felt responsible for the condition of machines and tools. The maintenance of discipline was in consequence made more difficult.

Since the middle of 1931 the government industries in the Union of Socialist Soviet Republics have returned to the uninterrupted 6-day week. Aside from the revolutionary holidays this means that the year is divided into 61 "weeks" with 305 working days and 61 days of rest. Since the working day consists of 7 hours, a year thus has 2135 hours of labor, which compares with 2080 hours of labor on the basis of the 5-day week as understood in western Europe and the United States, with 2288 hours on the basis of the 5½-day week of 44 hours and with 2496 hours on the basis of the 6-day week of 48 hours. In the seasonal occupations and the building trades production is often carried on uninterruptedly under the 6-day week by staggering the rest day. While the 7-hour day is the normal one for adult workers, the 6-hour day prevails for minors, who in 1929 constituted nearly 6 percent of employed workers.

In the economically backward countries of Asia and Africa the hours of labor are very long. While the conditions in customary agricultural and handicraft pursuits approximate those of mediaeval Europe, capitalist mining and manufacturing enterprises reproduce the worst aspects of the industrial revolution. The former comparatively low hours of labor have everywhere been increased; legislative regulation is insignificant and the labor movement weak. In 1927 an investigation in China revealed that in the factories of Peking, Hankow and Shanghai the customary working day consists of 12 hours with many workers toiling 14 and 15 hours. Day and night shifts are prevalent and many factories grant no day of rest; half an hour is allowed for the noonday meal and there are only 3 to 5 holidays yearly. This excessive working time prevails also for women. An official investigation of wages and hours in Greater Shanghai carried out in 1929 established that the working time of women in cotton spinneries averaged 12 hours per day. Children work as a rule the same number of hours as adults and in some cases have an even longer day than men; thus in printing establishments men worked on the average 8.4 hours, while the children's day extended to 10.2 hours.

Japanese labor works particularly long hours. This was recognized by the Washington convention, which set the working week for Japan at 57 hours and for some industries even at 60 hours. Despite this important concession the convention was not ratified by the Japanese government. At present the working day of women and of minors under 16 in establishments subject to the factory law is limited to 11 hours, which includes a rest period of 1 hour. Until August 31, 1931, spinneries and silk factories producing for export were allowed to employ women and children on the basis of a 12-hour day including an hour's rest pause.

The Washington convention contains also special provisions for India's benefit. It permits an 11-hour day with a 60-hour week; minors between the ages of 12 and 15, however, are allowed to work only 6 hours daily. It forbids overtime and night work for women and children, except in canning and curing, and limits the hours of miners working underground to 54 per week. Although the convention was ratified by the government of India, the limits set by it are frequently exceeded. In 1929 the Royal Commission on Labour in India recommended a reduction of hours in factories to 54 per week and

10 per day; a working week of 60 hours is to be the absolute maximum allowed only in exceptional cases, while the working day of children is to be limited to 5 hours.

Because of its distinguished history in the field of wage and hours policies special mention must be made of Australia. Since the second half of the nineteenth century it has been ahead of all other nations in reducing the hours of labor. The 8-hour day began to spread around 1870 and was customary prior to the World War. By the legislation of 1925 the 44-hour week was introduced in New South Wales. The standard 48-hour week was restored by law of June 16, 1930, but in December of the same year the new labor government went back to the 44-hour week. Since September, 1931, Western Australia has a 44-hour week, while Queensland is still on a 48-hour basis. Post-war statistics on actual working time in all occupations, excluding agriculture, animal husbandry and shipping, are presented in Table XI.

TABLE XI

AVERAGE WEEKLY HOURS OF LABOR IN AUSTRALIA,
1914-29

| END OF YEAR | ADULT MALES | ADULT FEMALES |
|-------------|-------------|---------------|
| 1914* | 48.93 | 49.08 |
| 1921 | 46.22 | 45.69 |
| 1922 | 46.38 | 45.82 |
| 1923 | 46.70 | 45.98 |
| 1924 | 46.66 | 46.02 |
| 1925 | 46.44 | 45.78 |
| 1926 | 45.57 | 44.94 |
| 1927 | 45.46 | 44.94 |
| 1928 | 45.27 | 44.79 |
| 1929 | 45.34 | 44.79 |

Principles. The nineteenth century writers on the hours of labor problems were divided into two camps, those siding with employers and those with employees. Opponents of shorter hours, who drew their theoretical arguments from the works of the classical economists of the first half of the nineteenth century, stressed the purely economic aspects of the problem; they admitted that shortening the working day was socially desirable but doubted whether such a measure was economically practicable and opposed arbitrary uniform regulation of the hours of labor. Social reformers, on the other hand, were convinced that the existing hours of labor were altogether too long and could be reduced without entailing harmful economic consequences; such a reduction promised in their

opinion a decided improvement in the hygienic, cultural and social conditions of the working classes. The ideological father of this orientation was Robert Owen.

In 1833 Owen formulated for the Society for Promoting National Regeneration several arguments in favor of the 8-hour day (*Crisis*, vol. iii, p. 125). He argued that if the right to exist be granted to the weak as well as the strong, then 8 hours constitutes on the average the longest period of physical exertion of which a human being is capable without impairing health, intelligence, the sense of moral values and happiness, the maintenance of which is in the true interest of every human being. He believed moreover that modern inventions in chemistry and mechanics make it possible under appropriate arrangements to produce in an 8-hour day an amount of commodities entirely sufficient for all. And, finally, he contended that no human being has the right to demand that others work more than is needed for the good of humanity in general merely for the purpose of enriching himself by impoverishing others. It is obvious that these are arguments not merely for the 8-hour day but for shortening the working day in accordance with technical progress, a thesis which is more clearly stated in his later contributions to the discussion.

In addition to the moral and social factors, of major importance to Owen, he brought forward also two considerations of an economic character; namely, that longer hours have become unnecessary because of technical progress and that "under appropriate arrangements" it is possible to increase productivity by reducing hours. As time went by the latter argument acquired increasing force. A shortening of hours without an increase in the productivity of labor would necessarily decrease the social product and, should the distribution between capitalists and workers remain the same, result in a proportional reduction of the earnings of both capital and labor. Under these conditions a reduction of hours could not take place without a corresponding adjustment of wages, a prospect which made Karl Rodbertus the sworn enemy of legislative regulation of hours on the English model. Evidence began to accumulate, however, which indicated that the decrease in hours of labor was followed by an increase in productivity and that the workers earned more in the shorter than in the longer working period. The causal connection between the two phenomena was accepted by some as a matter of course and emphatically

denied by others, but it was not objectively investigated until the early years of the twentieth century.

At that time Ernst Abbe, pioneer in the scientific research into the problems of working time, established on the basis of experience in the Zeiss works in Jena the three factors which caused fatigue. He traced one part of fatigue to the magnitude of the output, or to the physical expenditure of labor power; the second factor is the speed with which work is performed, the fatigue increasing only after a definite speed limit is passed; the third factor, responsible for passive fatigue, is the length of time during which the worker must sit or stand at his machine regardless of whether the time is productively occupied. The second and third factors in fatigue are, according to Abbe, of primary importance in determining the "correct" length of the working day. Thus the shortening of the working day would result in an increased output so long as the gain due to the longer rest period and to the saving of energy by shortening unused time at the bench is greater than the loss of energy required by the acceleration of the working tempo. On this basis Abbe believed that for at least 75 percent of the industrial workers of Germany the correct working day ought to be 8 hours or less.

The general reduction in the hours of labor in Europe after the World War put the conception of lower hours of labor to a severe test and transformed many supporters of the short working day into its opponents. This can be explained by the unusual circumstances under which the reduction of working time was carried out in most European countries. It was a period of political, economic, technological and psychological reorganization. Government and industry in the various countries had to adapt themselves to the new conditions, which differed considerably from conditions prevailing during and before the war. Most countries were suffering from violent currency fluctuations; there was no fixed price level and profits depended not so much on correct cost calculations and competent management as on chance and the ability of the entrepreneur to adapt himself quickly to changing conditions. The productivity of labor declined from the pre-war level. Whether this was due to poor organization of work, to an overcrowding of establishments with superfluous workers caused by the demobilization of the armies, to the physical obsolescence of the equipment or to the psychological aftermath of the war, European

employers charged it to the arbitrary reduction in labor hours and nicknamed the cause a "wave of laziness." A questionnaire by the International Labour Office about the new conditions of production elicited numerous complaints from employers regarding the effect on production of the 8-hour day. The inquiries made by the governments of various countries during the years 1919 to 1922 had similar results. Not only did this seriously shake Abbe's theory of the optimum working day, but it likewise discredited the social reform policy which had prevailed before the war.

Karl Diehl, the typical academic representative of the new orientation in Europe, asserts that there can be no such thing as a normal working day in the sense that an optimum of labor intensity is reached in a given number of hours. Theoretically Diehl is willing to recognize maximum limits to a working day only from the hygienic and cultural standpoint. Practically, however, this recognition is of no great importance, as in his opinion a working day of 9 or 10 hours is not excluded by reasons of health, while a cultural maximum working day constitutes a luxury which a country cannot always afford.

A more thorough analysis is offered by Otto Lipmann, who also distinguishes three aspects of the problem: the cultural, the hygienic and the economic. In his opinion a cultural maximum working day does not admit of specific limitations. A healthful maximum working day is defined by the fact that each worker must have at least sufficient time for rest and sleep fully to restore the energy expended during one working day before the beginning of the next. Lipmann thinks that this limit is continually being exceeded. The economic optimum working day is that which results in the maximum daily output. That is, if the length of the working day is x , the daily output z and the rate of output y , the economic optimum working day is determined by that value of x which makes the value of $z = x \cdot y$ a maximum. Lipmann believes that an increase in the length of the working day results in a somewhat less than proportional decline in the rate of output, the relation obtaining between the changes in their variables being expressed as follows: $(x_m^2 - x_n^2)/(y_n^2 - y_m^2) = \text{constant}$. If E signifies the length of a working day lasting until complete exhaustion has taken place, or the maximum value of x (a point at which y declines to zero), and P the output that can be obtained when the worker is completely recuperated, or the maximum value of y

(with a corresponding value of zero for x), then $E^2/P^2 = (x_m^2 - x_n^2)/(y_n^2 - y_m^2) = \text{constant}$, and $(x^2/P^2) + (y^2/E^2) = 1$ on the basis of the expression above. It follows that $y = (E\sqrt{P^2 - x^2})/P$ and $z = (Ex\sqrt{P^2 - x^2})/P$. The value of x which will make z a maximum is $P/\sqrt{2}$ and the maximum value of z is $PE/2$. In other words, the length of the economic optimum working day is about seven tenths of the physical maximum possible, and the maximum daily output which can be kept up over a long period is a half of the product of the highest conceivable rate of productivity by the length of the physical maximum working day. The validity of these conclusions depends entirely on the relationship between the changes in the length of working day and in the rate of productivity postulated in the first expression above.

The conclusion to which Lipmann comes is that the friends of shorter working time would strengthen their position if they admitted that there can be no one economic optimum working time applicable to all countries, all industries, all establishments and all workers. Having admitted this they could press with all the greater emphasis the view that in the case of many industries the shorter working time would in all probability approximate more closely the economic optimum and that if only because of cultural reasons a maximum working day should be demanded for all workers. Moreover they could justly hold that even where longer working time would seem economically profitable it will not turn out to be so unless the wages of the workers are raised to allow for an increase in their working capacity and their will to work. At any rate there is no doubt that the experience gathered of recent years proves that productivity does not increase appreciably in every instance with a reduction of working time. Where productivity was increased, the net result was achieved very slowly and indirectly because of technological progress stimulated by the shorter working day and relatively high wages. Working time is only one element in the complex of conditions determining labor productivity; the effect of its variations cannot be studied without taking account of adjustments in the other factors.

More recently the reduction of hours has been advocated on other grounds—the establishing of a balance between production and consumption not by increasing production but by increasing consumption. It is argued that working time must be reduced in order to give the workers

more leisure for increased consumption, which in turn is a prerequisite for increasing production. This new conception first became popular in the United States but has since spread also to Europe. The main problem is not so much a shortening of the working day as the limitation of the working week to only 5 days; Saturday, it is maintained, should be free from work so as to permit the workers an uninterrupted rest period of approximately 63 hours. This conception is not as new as it appears; in 1865 Ira Stewart, in arguing for the 8-hour day, said: "... men who labor excessively are robbed of all ambition to ask for anything more than will satisfy their bodily necessities ..." (quoted in *A Documentary History of American Labor*, ed. by J. R. Commons and associates, vol. ix, Cleveland, 1910, p. 285), and insisted that reduction of the hours of labor would stimulate consumption and consequently production as well. In recent years a group of employers, among whom Henry Ford is the most conspicuous, have argued that shorter working time is necessary in order to afford the workers an opportunity to enjoy the consumption of commodities which they have been instrumental in producing, thus insuring a balance between production and consumption. This viewpoint was adopted in 1929 by the President's Committee on Recent Economic Changes, which said in its report: "Closely related to the increased rate of production-consumption of products is the consumption of leisure. It was during the period covered by the survey that the conception of leisure as 'consumable' began to be realized upon in business in a practical way and on a broad scale. It began to be recognized, not only that leisure is 'consumable,' but that people cannot 'consume' leisure without consuming goods and services, and that leisure which results from an increased man-hour productivity helps to create new needs and new and broader markets During the period covered in the survey the trend toward increased leisure received a considerable impetus" (Conference on Unemployment, 1921, *Recent Economic Changes in the United States*, 2 vols., New York 1929, vol. i, p. xvi).

At the same time organized labor in the United States urged shorter working time in the form of the 5-day week from another angle—to offset the growth in technological unemployment. Between 1929 and 1931 the 5-day week was also urged as a means of restoring prosperity by increasing employment and wages. In both formulations shorter working time is proposed as a means of

maintaining the balance between production and consumption.

In a time of rapid technological progress the emphasis is not so much on a further increase of productivity as on maintaining the proper economic balance. This is also reflected in the new point of view concerning the effect of a shorter working day on the economic system. In any event the emphasis has shifted from the number of hours in a single working day to the number of days in the working week; in this new form the problem of the duration of working time has once more been posed in the form which it assumed in the period prior to the rise of capitalism.

HOURLWICH, ISAAC ARONOVICH (1860–1924), Russian-American economist and publicist. He was born in Vilna and studied at the University of St. Petersburg and the Yaroslavl law lyceum. Exiled to Siberia for revolutionary activities, he escaped to America in 1891. Several of his writings attracted attention in Russian translations and after the 1905 revolution he returned to Russia and ran for the first Duma, but his candidacy was canceled by the authorities and he was forced to return to the United States.

Hourwich was one of the earliest American economists admittedly of the Marxian school of thought, and particularly in his early writings he belonged to the orthodox wing of that school. His doctor's dissertation, one of the first accepted in economics by Columbia University, is a Marxian interpretation of Russian agricultural developments. His articles in the *Journal of Political Economy* were a pioneer effort to determine quantitative distribution of American population according to economic class on the basis of census data. He contributed numerous articles on economic and political questions to socialist periodicals. In his later writings he considerably modified his point of view. He frequently advocated cooperation of socialist and labor groups with progressive and radical bourgeois elements, the formation of a labor party which should not be exclusively socialist in principles and even the formation of a third party on general progressive lines.

Perhaps his most important economic work was *Immigration and Labor*, a penetrating analysis of the reports of the Immigration Commission leading to conclusions diametrically opposite to those of the commission as summarized by Jenks and Lauck. He argued that free immigration instead of representing a dangerous competition to American labor was an important factor in rapid industrial development and largely responsible for the growth of an active American labor movement. These conclusions were severely criticized by many American economists.

His greatest contribution to American life was through his journalistic activity, and he was considered the most important Yiddish publicist in America. Temperamentally somewhat unsuited to organizational activity and generally regarded as somewhat unstable in his economic and social views, he always fulfilled the role of questioner and critic.

HOUSE AND BUILDING TAXES. The house, or building, tax is a tax on the earnings derived from the ownership or use of buildings. In its pure form it is a tax in rem levied on the object and assessed according to objective criteria usually without regard to the personal status of the taxpayer. Frequently, however, the tax assumes the form of a levy on rental expenditure imposed on the tenant, in which case it approaches the character of a direct consumption tax. The modern building tax is to be distinguished from the house taxes levied in the Middle Ages and in early modern times, for such taxes aimed to reach the entire taxable capacity and the house was merely singled out as a convenient index of taxpaying ability. It is further to be distinguished from taxation of buildings, which forms an integral part of the general property or real estate tax. The building tax is frequently used along with many other similar taxes on specific sources of income to fill the place of a general income tax. Where the building tax is resorted to in addition to a general income tax the former is intended as a means of subjecting income from property to a heavier tax burden.

Modern building taxes are traced to two sources. Some evolved out of the French chimney tax—a sort of poll tax imposed on the members of one household. The chimney tax was also introduced in England but was transformed into a classified window tax in 1696 and finally repealed in 1851. The English window tax served as the model for the French door and window tax which was introduced in 1798 and abolished in 1917. The tax was originally of general income tax nature with the doors and windows used as presumptive criteria of ability to pay, but it gradually evolved into a specific tax on earnings derived from houses. In the meantime another tax was introduced in England in 1778; this tax levied on the annual rental of the premises was repealed in 1834 but reintroduced in 1851. The tax known as the Inhabited House Duty is levied on the occupier of the premises.

More frequently, however, the building tax is traced to the thousand-year old land tax. The

process of separation from the land tax, first in the form of a special levy upon land covered with buildings and later as an independent tax on the building itself, extends all through the nineteenth century and still continues today. At the present time there are even tendencies toward a retrograde development in reuniting the land and building taxes.

The object of the building tax—the taxing of the earnings derived from buildings—may be achieved either directly by assessing the actual or estimated annual yield or indirectly by taxing the value of the building. In some countries the buildings are classified according to type or location of buildings or according to the number of stories, doors and windows. In still other countries the buildings are assessed according to the size of the area they occupy. Depending then on the selection of the taxable base the tax may assume the form of a building yield tax, a building value tax, a classified building tax or an area, or surface, tax.

Where the annual yield is selected as the taxable base, the tax may be assessed with the aid of a rental cadastre which registers actual rentals from year to year and estimates the rental values of buildings occupied by their owners by comparison with rentals charged in similar buildings. In some cases the assessment may take the form of an individual declaration of the house owner of the actual rent received.

The tax may be levied on either gross or net yield. The former is the simpler, the latter the more accurate measure of taxable capacity. It is, however, practically impossible to determine the actual net yield by general principles applicable to all taxpayers, as the amounts charged to depreciation, repairs and amortization differ almost from case to case. On the other hand, assessment on the basis of an individual tax declaration, taking into account all individual deductible charges and the checking of these items, would involve an expense which would absorb a considerable portion of the tax yield. Consequently fiscal practise in most countries dispenses with the determination of the actual net yield and either confines itself to a tax on gross yield or provides arbitrary allowances for depreciation and similar charges in the form of a lump sum or proportional fraction of the gross yield. While such crude methods are harmless in cases where the general income tax or the general property tax forms the major portion of the tax burden and building taxes are of subsidiary nature and assessed at low rates, the crude assess-

ment methods may lead to grave inequalities in the case of high tax rates.

Where the value of the building is taken on the basis of assessment, fiscal practise resorts to taxing either market value as expressed in current transactions or earning value as ascertained by capitalizing the actual or estimated income at the prevailing rate of interest. While in a perfect market the two values are identical and under stable market conditions they tend to be equal, there may be wide discrepancies between the two in a period of fluctuating economic conditions; a fluctuating interest rate may lead to the imposition of an unjust tax burden. This of course may be obviated by having the legislature prescribe a definite capitalization rate.

The classified building tax is of merely supplementary nature; it is used in addition to the building value tax or more usually the building yield tax and applies to buildings which do not lend themselves readily to other forms of building taxation. This tax is suitable primarily to the rather uniform conditions in rural districts. When applied to urban conditions it usually requires too elaborate and complicated classification schedules. The French door and window tax was classified according to the locality of the building and the number of stories, doors and windows. The Austrian house tax of 1882 distinguished sixteen classes graded according to the number of dwelling rooms with a different rate for each class. The Hungarian house tax of 1920 differentiates three classes of buildings according to the town in which they are located with a further differentiation of ten subclasses according to the number of rooms.

The term area, or surface, tax designates a building tax based upon the size of the building site together with the accessory ground such as courtyard, garden and the like. The ordinary area tax is the most primitive of all building taxes and is used only under the simplest and most uniform conditions usually as a supplement to another form of building tax. A variant of the area tax is the so-called classified area tax existing in several of the Austrian provinces. It is levied on industrial, commercial and transportation buildings and on the ground used for storage and other purposes. The rate applied to the built up area is differentiated according to the number of stories, the character of the building (main or auxiliary) and the class of town in which the buildings are located.

A unique type of building tax is presented by the so-called building revaluation taxes (*Ge-*

bäudeaufwertungssteuer) which were introduced in the various German states after the stabilization of currency in 1924. The tax is levied on the annual rental and is intended to capture for the state some of the benefits accrued to the mortgagors by virtue of complete depreciation of their mortgage indebtedness during the inflation period. The considerable tax yield is in part applied to the promotion of building construction and in part merged with the general revenue of the state.

The practise of exempting certain types of building from taxation has been frequently resorted to in many countries. Apart from general exemption of buildings devoted to religious, educational and charitable purposes economic and social considerations compelled many countries to exempt new buildings as a stimulus to construction, thus alleviating the housing shortage. In some countries agricultural buildings are assessed at a lower rate to alleviate the position of the farmer. In others manufacturing plants are favored in order to stimulate industrial development. The single tax experiment in the north-western provinces of Canada implied the general blank exemption of all improvements.

In tracing the incidence of building taxes it is advisable to differentiate between cases where a tax of this sort has existed for a long time and those in which a tax is suddenly introduced or greatly increased. Building taxes which are levied on a building for a long time in about the same magnitude act as a capital burden and are usually capitalized and deducted from the purchase price by the buyer of the building. On the other hand, the introduction of a building tax or the sudden rise in the rate of the existing tax involves a corresponding reduction of the net yield and of the value of the property for the owner, who consequently endeavors to relieve himself of the loss by raising the rents. It is obvious that the tenants resist this endeavor. The extent to which the building owner succeeds in shifting the tax to the tenants depends upon a large number of factors, the most important of which is the condition of the housing market at the time. In times of housing shortage the shift of the burden to the tenants will occur sooner than when there is a liberal supply of housing facilities. If a building tax is levied on the tenant, it is but seldom that he succeeds in shifting it to the owner; and a tax shift is obviously out of the question when the owner is taxed for the building which he himself occupies. With regard to buildings used for trade or agriculture the

building tax burden represents a factor in the cost of production and can be recouped under normal price conditions in the sales price of the products and thus shifted to the consumer.

HOUSING

EUROPE. *Early History.* The history of human habitation is integrally bound up with the social and economic history of mankind. Rising originally out of the elementary need for protection from wind and weather, the dwelling comes eventually to provide the framework for the development of the primary form of social life—family life. When permanent settlement supersedes nomadic existence, the dwelling becomes also the workshop, until with advancing industrialization there occurs a separation between home and shop. At the same time the differentiation within society on the basis of wealth and other criteria relevant to the stage of development leads to wide variation in the form of dwelling adopted by different members of the community.

Already at the very beginning of history there may be found two types of human habitation which despite all subsequent evolution have retained their characteristic contrasts: the small cave which sheltered a single family and the larger cave in which several families sought refuge—the one-family house and the multi-family house. When man begins to build his dwelling, the material he employs is determined by conditions of climate, topography and vege-

tation. First the most accessible types of wood are used; later minerals or materials obtained by processing textile fibers are employed. Wilhelm Wundt, who describes the most important types of primitive dwellings in his *Völkerpsychologie* (vol. vii), points out that their form is influenced by certain general aesthetic requirements. The simplest geometric patterns—the circle, the oval, the triangle or the quadrangle—are preferred. Thus in the most elementary dwelling forms—the tent and the spherical and beehive huts—the circle is combined with the triangle; the quadrangular house usually has a triangular shaped roof.

The form of the dwelling is also affected by its size, or the type and number of occupants for whom it is intended, which in its turn is conditioned by the prevailing social order. The men's house is characteristic of an organization of primitive social life which is dominated by the principle of male associations; in societies of this type the family huts are inhabited only by the women, the children and the aged. With the introduction of polygamy and the ensuing stratification of society the men's house disappears. The powerful and the rich own several huts, providing living quarters for their wives and children; scattered at first, they are later concentrated within a limited area forming a farmstead which includes also storerooms, slave quarters and animal stalls. But the socially inferior and the poor live in single modest huts. The men's house becomes a public building and serves either as a meeting place or as the dwelling of the chief. The multifamily house, on the other hand, is found where several families maintain under single leadership a closely knit communal life; the characteristic form of the primitive multifamily house is the long house with a separate division for each family.

Out of these original forms of human habitation developed the purely agricultural settlement, the village, and the center of primarily industrial activity, the city, in which at a comparatively early date the various trades were assigned particular sections. In the cities of antiquity the one-story, one-family house was most common; planned arrangement of dwelling houses came only at a later date. The cities of the Babylonian-Assyrian Empire were laid out on a very large scale; streets and roads were well constructed and there were water pipes and sewers. But great masses of people were crowded within the city walls and the individual dwellings, providing only the barest necessary space, were arranged

alongside one another haphazardly. It was not until the fourth century B.C. that there emerged in Greece a systematic city plan, with distinct residential areas and districts for public buildings and temples; Greek cities were also provided with an adequate water supply and sewage systems, the rational use of which was insured by legislation.

More and better information is available regarding housing conditions in ancient Rome, particularly during the period of the empire. The city occupied a comparatively small area; as its wealth increased, the greater the space taken up by public edifices, temples and dwellings of the wealthy, the more crowded were the districts allotted to the working population. With the development of a money economy speculation in building sites and residential buildings became very extensive. Land was therefore utilized to the utmost by the erection of as many stories as possible and by reducing the size of rooms; houses were filled with people from garret to cellar. Rentals were continually rising and the profits of landlords, their lessees and sublessees increased together with the evils resulting from crowding in inadequate quarters. The extent to which the much admired water supply and sewer system of Rome benefited the dwellings of the poor is questionable. Similar conditions are reported for Byzantium.

In the history of housing there is no apparent continuity, at least for central and western Europe, between the Roman period and the Middle Ages. The Roman settlements in western and southern Germany and in Gaul fell into ruin; and the Germans, prevented by superstition and fear of ghosts from moving into the Roman houses, erected their wooden huts alongside the Roman villas. Thus out of the conditions of primitive peasant life developed an entirely new housing system, closely related to the feudal order of the Middle Ages. For some time the largest settlements were those of vassals and serfs attached to manor houses, cloisters and castles. Cities with a distinctly urban form of life appeared only in the twelfth and the thirteenth century. Here with the growing extension of industrial activity developed a new bourgeois class which knew how to preserve its freedom and which shaped the plan of the city according to its own living and working requirements. At first the cities were spaciouly laid out and offered their inhabitants the possibility of combining agriculture with the exercise of their trade as merchants or artisans. In the twelfth and

the thirteenth century land in the cities was owned largely by great landowners—the king, the nobility, the clergy or the urban patriciate; later the progressive subdivision of the extensive areas of mediaeval cities into individual small home parcels was accompanied by the complete separation of ownership of land and of buildings. As early as the thirteenth century house owning became a trade, since at the time when interest bearing loans were prohibited it offered an opportunity for advantageous investment of capital and profitable speculation. If favorable location or the special value of the building enhanced site value, this increase accrued to the building owner and not to the landowner, as was provided in the Roman law later introduced; the landowner received only a small lease rent, which was fixed once and for all. As new population streamed into the cities, city land hitherto employed for agriculture was settled or the city fortifications were placed at a greater distance from the center.

These conditions lasted only while the flow of rural population into the city was comparatively limited. When “the sheep crowded out the people” and because of the transition from grain farming to pasture farming, as in England, or for other reasons the influx of outsiders into the cities became large, attempts were made to limit the migration of persons without means. Henry II issued such prohibitions for Paris in 1149 and Elizabeth decreed similar restrictions for London in 1580 and 1593. In the meantime the extension of the cities had become a much more difficult problem, for with the perfection of artillery the city had become a fortress and every shift of the strong walls and bulwarks was very costly. Soon the old reserve of open spaces and gardens within the cities vanished; buildings increased in height and in number of stories; and the walled city area became ever more crowded with buildings separated by the narrow winding streets still characteristic of central districts in the cities which have escaped demolition since the Middle Ages.

But the most important influence upon the growth of the cities and the development of housing was the change in the constitution of economic life, which set in with the increasing extension of the market and the intensification of money economy and which led to the development of a mercantilist economic policy. The rulers of mercantilistic states, who sought to further the production of goods for export, endeavored to encourage population and urban growth by every means at their disposal. People

who had a trade were attracted to the cities by offers of special liberties, privileges and loans; the same purpose was served by an extensive policy of building, which reached its climax on the continent during the eighteenth century and which was encouraged by such measures as grants of sites, building material and even building subsidies; at the same time the prices of dwellings built as a result of such aid were limited by administrative regulation. Building activity in the age of mercantilism had thus a certain methodical character.

From the Industrial Revolution to the World War. The industrial revolution effected a profound change. The development of large factory industry brought about the separation of the dwelling from the workshop and the subdivision of the city into factory, business and residential districts. In order to accommodate the working population the areas lying outside the cities were rapidly settled, and new urban developments soon clustered about outlying factory establishments. Moreover this entire movement, often extremely rapid, took place in an environment in which the free interplay of economic forces was not hindered by the slightest endeavor on the part of public authority to prescribe regulations of settlement and housing conditions. In accordance with the prevailing principle of liberalism housing was left entirely to free competition and the exigencies of the profit motive.

The results of this structural change in the economic life were manifested first in England, where the numerical ratio of agricultural laborers to industrial workers was reversed during the half century from 1790 to 1840. Where housing facilities in industrial cities did not meet the requirements of the influx of workers, the old nucleus of the city was surrounded by growing suburbs. When builders for profit failed to meet the demand, the employers themselves often erected dwellings for their workers, thus increasing the dependence of the worker who lost his dwelling together with his job. Landlords exploited the situation by endeavoring to house as many people as possible in the smallest area and at the lowest cost, thus giving rise to the frightful housing conditions characteristic of the industrial revolution and still prevailing to a very real extent today. In England the lease system—the erection of dwellings under long term leasehold on land belonging to a large landowner—adversely affected housing conditions, for the owner of the house let it fall into disrepair as the termination of his lease approached. This sys-

tem also favored the construction of small houses, a type of dwelling which has remained predominant in England despite the advantages that the erection of mass tenements might have offered. The well to do classes of the population also held resolutely to the small house, purchasing it as their own property.

On the continent, where the industrial revolution set in some decades later, the development of housing took a different turn. Here the small house was displaced by the multifamily house, the former type persisting to an appreciable extent only in Belgium and the Netherlands. Some idea of the prevalence in various European cities of the two major types of housing, as measured by the number of occupants per house, may be gained from Table I, which covers the period following 1860-70.

TABLE I

NUMBER OF OCCUPANTS PER HOUSE IN SELECTED
EUROPEAN CITIES

| | |
|--------------------------------------|------|
| Sheffield, Birmingham and Manchester | 4.8 |
| London (inner districts) | 7.9 |
| The Hague | 6.5 |
| Amsterdam | 13.4 |

Even within the multifamily house the well to do household had at its disposal a spacious apartment of many rooms. The typical working class family, on the other hand, could not afford a dwelling of more than two or three rooms. In many regions of central Europe the worker was almost inevitably condemned to live in a crowded tenement house. The tenement was designed for the most intensive exploitation of the available dwelling area. Therefore as many stories were piled on one another as were allowed by construction technique and considerations of building safety; even cellar and attic were used for dwelling purposes. Plots were completely utilized; the structure was divided into front and rear sections and only the meagerest space allotted to the small courtyards. The tenements were strung together in extensive blocks.

In England, where the small house maintained its position as the outstanding type of dwelling, there was always a shortage of houses for the poorer classes because their income was too low to afford a rent which would meet the costs of new building. Moreover the construction of small houses required the continuous enlargement of the city area and the extension of the urban traffic network, which created difficult technical problems. Yet the wealth of the country made it comparatively easy to secure capital for building purposes, and the construction of privately owned dwellings was aided considerably by the creation of building and loan associations (*q.v.*). Since their origin in the eighteenth century building societies have extended the scope of their activity over the entire country, obtaining their loan capital partly by the issue of shares and partly by accumulation of savings, and were more than any other single factor responsible for the extension of home ownership in England.

The financing of housing construction on the continent presented much greater difficulties, as land had to be bought outright and the mass tenement was the prevailing form of housing, especially in the large cities. Generally speaking the price of land depends upon its scarcity and upon the rent paying ability of those in need of housing. Where the purchasing power of the residents is limited, land is intensively exploited by a system of mass tenements, and the price of land rises as a result of the growing percentage of rent accruing to the land. Such an increase in the value of urban land occurred in all parts of Europe as industrialization progressed. In this process the ups and downs of the business cycle played an important part.

In periods of prosperity with their greater requirements for labor the attraction of the industrial centers increased and the demand for housing grew enormously; at the same time housing construction could not keep pace with demand, declining rather than increasing because of the competition of industrial construction and other forms of capital investment. Wages did not rise as rapidly as building costs and interest charges, so that rents could not be increased sufficiently to make new construction profitable. Thus prosperity was regularly accompanied by a growing housing shortage, which led to increased overcrowding of the available dwellings; often working families took in lodgers in order better to meet the rising rents. In periods of depression, however, rents by no means decreased as rapidly as the costs of building and the interest rate.

Such a decline took place usually only where the population was stationary, as in many districts of France, or in localities from which important branches of industry had migrated. Since lower building costs during depressions were not reflected in a proportionate decline of rent, an extra profit was obtained from the exploitation of the tenement; and land values were raised correspondingly. The increase in land values frequently accrued to the benefit of land speculators, who although not responsible for the rise in rents timed the transfer of land from agricultural to residential uses so as to profit most from the discrepancy between rents and building costs. Thus rents and with them the price of land manifested an unmistakable tendency to rise in cities with an increasing industrial population—rents rising in the periods of prosperity and land values in the periods of depression.

In addition to a continuous rise in land values and attendant land speculation the development of continental housing was characterized by the fact that building was carried on as a rule by men with limited capital, who confined themselves to the erection of comparatively few houses. This situation favored the development of a complicated credit system with comparatively high costs; it included banking institutions, private individuals and real estate speculators as well as building contractors and building trades workers. Nor was the mortgage financing of completed new buildings adequately organized. The long term credits which mortgage banks, savings banks and insurance companies granted at a comparatively low rate of interest did not suffice to raise all the capital required for housing construction, especially since loans by these institutions were subject to a legal maximum—50 to 60 percent of the estimated value of the building (*see* LAND MORTGAGE CREDIT, URBAN). The builders did not usually retain permanent possession of the houses but sold them quickly and at the highest price obtainable. Thus the ownership of urban tenements was distributed among numerous persons who possessed only small capital of their own for which they were seeking the safest and most profitable investment. Their function was to squeeze as much income from their meager investment as possible; the rent laws of most countries insured this group of owners extraordinary superiority over economically weak tenants.

This system of housing construction satisfied the requirements of the well to do classes, although in time the private home was displaced

by the apartment house. For the large masses of the working population, however, there were only cheerless small flats in the slums of the modern industrial cities, in which it was difficult for a family to develop a decent home life. Misery and disease prevailed in these wretched areas and infant mortality was very high; as poverty compelled the letting of space to boarders, the requirements of hygiene and of morality were more and more neglected. The housing of certain groups of unskilled workers, casual laborers and families with many children was even worse; they were forced to inhabit damp, dark and airless rooms, cellars, garrets and structures not originally intended for residences. For workers in rural districts conditions were not much better, especially where the system of seasonal work was common; the temporarily employed laborers were very often sheltered in provisional dwellings without regard to sex.

A working class family had to expend a relatively large proportion of its income for rent—a percentage indeed which was inversely proportional to the size of its income. According to the available figures, which are not strictly comparable, the percentage of the average worker's income expended for rent before the World War was about 18 percent in Germany, Poland and Hungary, 16 percent in Great Britain, 12 to 15 percent in the Scandinavian countries, 15 percent in Austria, 12 percent in France, 11 percent in Italy and 10 percent in Switzerland. On the other hand, bourgeois families were much less burdened by rent (8 to 9 percent at most).

It was a comparatively long time before people became convinced that the development of large cities and the housing of the poorer classes could not be left entirely to the interplay of free competition. The first endeavors at administrative intervention were motivated by considerations of public health, since epidemics found a favorable breeding spot in the overpopulated districts of the large cities. Public authorities concentrated upon the three requirements of municipal hygiene—centralized water supply, sewage and paved street systems. Later appeared the idea, which had been slow to develop, that it was necessary to separate the business and industrial zones from the residential districts in accordance with a methodical city plan and to prepare for the growth of the urban area by plotting in advance the extension of municipal services. This resulted in the further requirement that all building plans be made dependent upon administrative approval. In England such legisla-

tive activity began with the Shaftesbury Act of 1851, which was followed by numerous legislative measures extending down to the Housing and Town Planning Act of 1909. The local authorities were entrusted with the duty of providing for proper sanitation, regulating the maximum height of buildings and the density of construction, preventing overcrowding of dwellings, forbidding the use of unlivable quarters and the like. They were empowered even to undertake the construction of houses if this expedient was deemed necessary to clean up the slums. The problems of city construction and of public health were followed attentively from the end of the nineteenth century on in Germany and Austria, where the action taken by public authorities paralleled the English development. Since the 1870's a number of German states have regulated in great detail such things as requirements of building and fire safety, height of buildings in various city sections, relation of occupied area to entire plot, exposure to sunlight and ventilation and height of ceilings.

Little thought, however, was given to the increase in building costs (and therefore rents) which such regulations involved. Although public bodies almost everywhere refused as a matter of principle to take care of the construction of the required housing themselves, far sighted municipal governments—particularly in Germany during the decades preceding the World War—endeavored by the systematic purchase of land in the vicinity of the city to meet the requirements for park areas and for the planned development of residential districts. Some municipalities also extended financial assistance to all organized effort in the cause of housing reform. Such activity was generally confined to private philanthropic associations, although not without occasional participation by employers interested in the welfare of their workers.

In the years immediately preceding the war national associations for housing reform and international congresses faced three leading problems. The first was the question of the reduction of land prices, for these were often blamed for the rise in rents. The proposals made in this regard varied from the comparatively conservative suggestion that at least a portion of the unearned increment be insured for the public by means of taxation to the radical demand made by the advocates of land reform that all municipal real estate be declared public property. Other supporters of housing reform regarded building costs as the determining factor in the progressive

rise of rents; therefore elaborate investigations were made of the feasibility of reducing building costs by the employment of cheaper building material, the introduction of new and simplified types of housing construction and so on. The question was also raised as to the feasibility of substituting the Anglo-Saxon system of small houses surrounded by gardens for the mass tenement so widespread on the continent without increasing the expenditures required for meeting housing needs. This problem was often discussed in the light of the relative merits of home ownership, which, it was argued, hampered the mobility of labor. Moreover detailed comparative inquiries seemed to show that the construction costs per unit of built up area in the case of mass tenements were smaller than those for private homes and that private home building as a general plan called for heavier expenditures for general transportation facilities, paving, lighting and sewage disposal. The defenders of mass tenements also pointed out that many of the evils associated with this form of housing could be eradicated by higher standards of sanitation and ventilation and by provision for common garden courts and playgrounds. Finally, a third group of housing reformers considered the system of financing to be the most important hindrance to an improvement of housing conditions. The proposals of this group dealt principally with a suitable change in credit organization.

Since experience in almost all countries had shown that the system of free competition was unable to produce a sufficient number of dwellings, well constructed and at reasonable rents, to meet the requirements of the working class, an endeavor was successfully made in many countries to solve the problem by other methods. In many cases industrial concerns were led to erect large non-profit making housing settlements which fulfilled all social and hygienic requirements. In this connection the rise of mutual building societies in many countries after 1900 is of particular importance. These were formed largely by persons suffering from the housing shortage (workers, clerical employees, civil service employees and the like) and were aided in increasing degree by many municipalities, by state legislation and at times by the managements of large factories. In central and southern Europe they assumed most commonly the form of a building cooperative, which often retained the title in the houses built by it and whose membership carried a double liability. Special difficulties, however, centering in financing, manage-

ment and the like, hampered the movement so that its progress up to the beginning of the war was rather disappointing. Among the building societies there was a special group which came to be influenced by the ideas of the land reformers. Its purpose was the establishment of garden cities patterned after those laid out in England, where the title to the land, garden plots and other communal facilities rested in the association or the municipality while the homes were privately owned. Garden cities, however, continued as isolated phenomena both in England and on the continent.

Although the efforts of the housing reformers succeeded only to a limited degree in eliminating housing shortage and housing poverty, it is to their credit that by the creation of new types of dwellings and model housing projects they paved the way for noteworthy progress in raising the standard of housing. As long, however, as housing construction was left largely to private initiative, a lasting and thorough improvement of conditions could be expected only from the progressive increase in the labor income of the masses.

The War and the Post-War Period. The World War introduced a radical change in the housing situation in virtually all European countries. Measures for the protection of tenants and for limitation of rents were adopted as emergency devices in all belligerent as well as in many neutral states. In France a moratorium on house rents affecting numerous groups was decreed at the very beginning of the war; this was followed by the prohibition of rent increases and limitations on the right of eviction. Similar steps were taken in Great Britain in 1915; in Denmark, Norway and Hungary in 1916; in Austria, Italy, Holland, Switzerland, Sweden and Germany in 1917. It was inevitable that such measures should bring about a complete stoppage of housing construction; in fact residential building was entirely forbidden in many countries during the war.

Even after the end of the war the prohibition of the adjustment of rents to the changed value of money was not repealed in most European countries, for it was feared that a sudden and very considerable rise in rents in accordance with the increased demand for housing might result in grave disturbances of income and more particularly of wage conditions. The results of this system of tenant protection differed according to the degree of currency depreciation which ensued in various countries during the post-war years. Where currencies were stabilized on a gold

basis within a short time, as in Great Britain and most of the neutral states, the percentage of family income allotted for rent was not reduced very appreciably; in Great Britain, for instance, it dropped from 16 percent to 11 percent. In these countries it was not very difficult to pave the way for a return to the free housing market by a gradual increase in the rents for older dwellings. In others, where the currency was stabilized often only after a long period of depreciation and at a level much below the pre-war rate, the percentage of income expended for rent dropped much lower (from 3 to 5 percent in Italy and from 3 to 7 percent in France, while conditions in Belgium, Czechoslovakia and Finland were similar). In Germany, Austria and Hungary, where inflation led to a complete depreciation of money and where rent ordinances were rigidly enforced, the proportion of family income spent on rent dropped to a tiny fraction. In these countries no interest was earned by capital invested in housing and the capital was consumed without any provision for its replacement. Losses to house owners and mortgage holders were given little consideration, since other investment values had also been reduced to very small fractions of their former worth. But the reduction of the rent percentage of income produced the desired result of preventing too great a drop in the standard of living and too large an increase in wages, which would jeopardize the competitive position of the domestic industries in the world market. The virtual elimination of rent made it possible for the members of the middle class, who had lost most or all of their income as a result of currency depreciation, to maintain their housing standards. In many cases they subleased the extra rooms of their comparatively large flats and received a much greater sum for the rent of individual rooms than was paid as rent for the entire dwelling. Under these circumstances private building was out of the question; the prices of building materials had followed the general trend of prices and in many cases had risen even more rapidly, and the increase in the interest rate due to the shortage of capital also added to building costs.

As a result of rent restrictions and the stoppage of building housing conditions remained fixed at the point which they had reached during the war. Anyone who had a dwelling kept it even though it no longer satisfied his needs, for rent played but a negligible role in the household budget. The housing market lost its ability to adapt supply to demand. At the same time the

demand for housing became unusually urgent in many regions: industry revived during the period of post-war prosperity, the number of marriages increased and there was considerable migration induced by the territorial changes following the war. The result was a most acute housing shortage and so far reaching an impairment in the mobility of labor that many needed industrial readjustments were greatly impeded. While on the average housing density declined in some countries, partly as the result of a changed age composition of the population, many dwellings were overcrowded as never before. Thus in 1919 the government estimated the most urgent housing needs in Great Britain to be 500,000 dwellings; in Germany, following a housing census in 1925, an official estimate put the shortage at 800,000 dwellings. In France, which also had a shortage of several hundred thousand dwellings, the chief problem was the reconstruction of the regions devastated by the war. The shortage of dwellings was also severely felt in Belgium, Czechoslovakia, Austria, Hungary, Italy and Poland. The estimates of private individuals, particularly those of the housing reformers, were of course considerably greater because they were based on higher housing standards. A rough outline of the extent of overcrowding in the post-war period is presented in an International Labour Office study. If the standard of overcrowding be an occupancy of more than two persons per room, then the figures for overcrowding in large city flats containing one to four rooms are:

| | |
|-------------------|------------|
| France | 6 percent |
| Germany | 7 percent |
| Belgium | 8 percent |
| England and Wales | 12 percent |
| Denmark | 14 percent |
| Sweden | 18 percent |
| Norway | 19 percent |
| Austria | 24 percent |
| Czechoslovakia | 32 percent |
| Finland | 44 percent |
| Poland | 49 percent |

It is obvious that housing conditions in eastern Europe were alarming; similar conditions doubtless prevailed in southern Europe (Italy and the Balkans). It must be noted that the figures presented above do not allow of strict comparison as they do not refer to the same year and as the term room is variously defined.

As the housing shortage continued and new construction was suspended, public authority was compelled to allocate available house space by a series of extraordinary devices. These com-

pulsory measures differed widely in the several countries, depending upon the intensity of the housing shortage and the degree of authority wielded by the government. The most common forms of distribution of dwelling space employed in central Europe were compulsory registration of vacant dwellings, prohibition of the use of dwellings for other than living purposes and allocation of available dwelling space to those needing housing by means of administrative permits issued only to persons proving the special urgency of their needs. These measures were repealed only gradually with the progressive diminution in the housing shortage.

In many central European countries, where the ideas of planned economy and of socialization were widespread after the war, the demand was put forward that the production and distribution of housing be governed by entirely new principles. Point was given to this demand by the fact that in the field of housing construction private enterprise had been virtually eliminated and that the house owner had been practically reduced to the status of a superintendent. Among the proposals most commonly advanced (especially in Germany from 1919 to 1921) was the transfer of ownership in houses to municipalities, public service corporations or tenants' associations, the last to be charged also with the construction of new buildings. All of these suggestions failed, however, to furnish an adequate solution of the problem of the permanent provision of housing and before very long they were largely abandoned.

Parallel to this movement but radically different from it in purpose developed another, which aimed at replacing the private builder by organizations of building workers. It was expected that the organization of workers into building guilds would raise their productivity and allow them to share in the profits. In Germany this movement achieved some success. In 1928 there were 130 guilds which had built or were building some 65,000 small houses, but they lacked the necessary capital and thus failed to fulfil the expectations of their founders. Similar attempts were made in other countries—France, Italy, Sweden and Austria—with but slight success. In Great Britain, where in the years 1920 and 1921 the government generously financed building, such guilds were able to function unhampered by lack of capital. In later years, however, with the cessation of government aid the guilds suffered heavily from the competition of private builders.

Apart from Soviet Russia the idea of the socialization of housing met with some success in only one European country—Austria. The municipal government of Vienna, controlled by the Social Democratic party, allowed rents to rise only to the extent necessary to cover cost of current maintenance. Since this caused a marked depreciation in house and real estate values in Vienna, it was easy for the municipality to increase its ownership of real estate, so that by the end of 1928 it owned about 15,800 acres. In addition it took over the provision of housing, the cost of new construction being covered in part by a special steeply graduated tax on the rents of the older houses. After 1923 the municipality succeeded in carrying out an extensive building program, the total cost of which was more than \$93,000,000. Until 1930 accommodations for about 38,000 families were erected in the form of large apartment houses containing chiefly two to three-room flats; these houses were for the most part united into blocks, laid out according to model plans and equipped with the necessary hygienic improvements. Moreover settlements totaling about 5000 small houses were built on the outskirts of the city. This construction program made up only in part, however, for the shortage of small dwellings. The rent of all dwellings erected by the city was set at a level to cover merely the costs of maintenance and management. Beginning in 1929 rents were raised gradually, so that by 1931 they reached about one third of pre-war rents. At the same time a special tax on rentals was introduced to provide funds to promote building activity throughout the country.

In Soviet Russia the changes in housing policy were much more radical. With the abolition of private property land and buildings became the possession of the republic. Private construction was forbidden and the obligation of paying rent abolished. For a while housing construction ceased entirely, and the available houses and dwellings fell into disrepair. No less than 20 per cent of all dwellings were unusable in Moscow at the beginning of 1924. Local organs were authorized to distribute the available housing space as they saw fit, the members of the proletariat of course receiving preference. The dwelling area allotted to a worker was set at 8 square meters; actually, however, even this small space was not generally available in the cities. In the metropolitan cities it became usual for all large flats to be occupied by several households. On the average there were 168 families for every 100

dwellings; the ratio was less favorable in Moscow, Leningrad and Kharkov.

The problems of housing policy, discussed so much before the war, reappeared in the reconstruction period in a much more intensified form. True, the problem of providing land at reasonable prices lost its former importance, since real estate values had dropped sharply with the fall in rental income. So much larger, however, loomed the rise in the prices of the two other component elements—building materials and capital funds. Except during the periods of unrestricted inflation, building costs practically everywhere were continually above the general price level. A comparison of building costs with an index of wholesale prices for two post-war years is presented in Table II; where figures for

building costs are not given, the index for prices of building materials and the hourly wages of building workers may be used. The figures for the various countries are computed on different bases and are therefore not comparable; nor are they perfectly accurate for each country by itself. Still they show clearly certain general tendencies: in a number of countries—Finland, Italy, Germany and Czechoslovakia—building costs and especially wages rose at the time when wholesale prices dropped or remained stationary; while in certain other countries, such as Belgium, they rose faster than the wholesale prices; in Sweden and Norway they declined more slowly than wholesale prices; while in Great Britain and the Netherlands although reduced much more than the general price level they still represent a larger increase over pre-war figures than general wholesale prices. A partial but probable explanation of this remarkable phenomenon is the fact that in so far as construction was aided by public subsidies no rigid profit and loss calculation was followed, which weakened the pressure upon the prices of building materials and particularly upon the wages of building workers. In certain instances the sudden launching of building projects generously financed from public funds actually raised the prices of building materials and wages. This was the case in Great Britain during 1920–21, where it led to extensive investigations and to the appointment of special commissions to control prices and to regulate the supply of building materials (1923 and 1925). It is also important that where credit out of the public treasury played a significant part in financing construction, residential building did not slacken in periods of prosperity, as it would under normal conditions, but continued to compete with industrial construction for materials and labor.

With the introduction of the New Economic Policy measures were taken to encourage the construction of new dwellings. In 1921 small houses with a value up to 10,000 rubles were returned to their owners and private individuals were again allowed to construct new small dwellings, being guaranteed the right of ownership of the building for a period of from forty-five to sixty-five years. Payments of water and light rates and of rent were reintroduced; rent was kept low, however, and scaled according to the earnings and social status of the tenant. Nevertheless, the housing shortage became ever more acute, largely on account of the rise in the urban population. In 1925 the government de-

cided upon an increase in rents for the purpose of insuring the maintenance of the existing houses, and rents were again raised in the two following years; in 1928 the expenditure for rent averaged 8 percent of the working man's budget. As the houses administered by the municipalities were particularly neglected, the formation of tenants' cooperatives to take over the house leases was favored after 1924. At the beginning of 1931 there were about 6,000,000 persons in these cooperatives, occupying about 35,000,000 square meters of housing area.

According to a census taken in 1927–28, 17.8 percent of houses used as dwellings were owned by the state; 81.8 percent (mostly primitive one-family houses of the urban and rural laboring population) were owned by private individuals; while 0.4 percent were owned by cooperatives. But almost all large buildings, containing no less than 46 percent of the total dwelling area, were the property of the state. The construction of new dwellings was controlled largely by the state authorities and by the building cooperatives (also financed by the state), which came into existence in 1924 and to which in 1931 some 400,000 families containing 1,500,000 individuals belonged. In 1929 of all the capital invested in new housing 52 percent was for state construction, 25.3 percent was for construction by cooperatives and 22.6 percent was for construction by private enterprise. The achievements of the cooperatives although slight so far have been on the increase. The expenditures for public housing construction rose from 419,000,000 rubles in 1928 to 582,000,000 rubles in 1930. On the other hand, the investment of private capital fell from 149,000,000 to 50,000,000 rubles. If the cost of a dwelling be estimated at 8000 rubles, there were only some 80,000 dwellings provided in the Soviet Union during 1930.

Among the buildings erected the two and multistory houses are increasing at the expense of the one-story type. As a rule the flats in the new buildings consist of from two to four rooms. A new type is the "house of collective living," designed for at least 400 persons and occasionally for as many as 800. While each occupant is provided with an area of 6 to 9 square meters for individual use, a great deal of space is allotted to communal activities, such as dining rooms, club-rooms, kindergartens, lecture rooms and solaria. Family life in such houses is supposed to be virtually eliminated and the position of the woman, thus emancipated from all household duties, is radically changed. According to recent programs,

after 1931 at least 50 percent of all dwellings to be erected will have no private kitchens.

Despite the ambitious plans for new building and for the laying out of model cities at the new centers of production the housing shortage has apparently increased during the past few years. At the beginning of 1931 the available dwelling area in 1920 cities was 171,000,000 square meters for a total population of 31,000,000, or a per capita area of only 5.7 square meters. Housing construction was hampered not only by lack of capital and by inefficiency of organization but also by the shortage of skilled labor and building materials and by inadequate transportation. It will doubtless be long before the general housing standard in Russia reaches the level considered adequate in western Europe.

Other countries which rejected socialist or semisocialist programs of housing construction could do no more than prepare for a return to the system of competitive building. After the currency was stabilized the rents of the old dwellings had to be raised gradually to the level approximating the cost of production of new houses. Some indication of the adjustment of the prevailing rents for old houses to the general price level is given in Table III, in which the rent index number is presented as a percentage of the corresponding index of retail food prices.

It is to be observed that by 1929 the average rent in Great Britain attained the level of retail food prices but remained below the level of building

costs. In Germany the rentals in old houses were raised by degrees to the general price level of consumption goods without, however, reaching the level necessary to insure a profit from private construction. At the same time a tax was imposed on rentals which appropriates to the municipalities and *Länder* a part of the increase, the remainder being sufficient to cover the cost of maintenance and management, to provide for interest and amortization on the revalorized mortgage indebtedness and to yield a fair return on the owner's equity. A part of the proceeds of this tax is used in extending financial support to new residential construction. In several other countries the permitted increase in rent is allocated in a similar fashion.

The attempts to combat high building costs were on the whole unsuccessful. England and many other countries endeavored during the period of inflation to regulate prices of building materials, but such efforts were soon abandoned. At times, however, municipalities or associations of cities took over plants in which they produced their own building materials or established agencies to purchase them. The endeavors to reduce the cost of construction by the use of new materials (e.g. steel, wooden bricks), by improvements in the methods of building (mass production of standardized parts), by the relaxation of building regulations and by the layout of large settlements consisting of standardized dwellings and houses were of greater importance. In certain countries, notably England and Germany, special commissions were created to study the rationalization of house building.

The provision of the necessary capital was even more of a stumblingblock than building costs, particularly in countries suffering from a general capital shortage, where the long term loans required for housing construction involved a comparatively high interest rate. The difficulties of this situation were increased by the disinclination, general among capitalists of the post-war period, to make long term investments. Thus public subsidies often proved an insufficient stimulus to private building, particularly in central Europe; states were sometimes compelled to supply part of the capital on easy terms.

Under such circumstances governments found it necessary to encourage new construction, which involved a number of decisions on matters of policy, such as that of raising housing standards or of housing in rural districts. The latter question was closely connected with the general problem of urbanization and of the balance be-

tween agriculture and industry. Since most countries suffered during this period from an agricultural depression, rural housing was generally neglected while governments concentrated on encouraging building in large cities and industrial centers. Although the methods employed in promoting residential building differed in the various countries, practically everywhere—in Great Britain as well as on the continent—local authorities embarked shortly after the end of the war upon a program of erecting small dwellings, in which they were frequently aided by the central government. Such direct participation in building gradually ceased; public bodies came in time to confine themselves to grants of financial aid to public service housing societies and to private builders. In Great Britain, the Netherlands, Scandinavia, Czechoslovakia and Germany the process was particularly marked. Single municipalities and their associations came to be concerned primarily with ascertaining the housing requirements of their localities, determining the type of housing needed, mapping out building programs in accordance with the available capital and labor, providing directly or mediating in the provision of financial aid and adopting measures for the maintenance of public health standards.

In Great Britain assistance provided by the local authorities soon enabled private builders to handle a considerable percentage of construction. In central Europe and the Scandinavian countries, however, public service societies, especially building cooperatives, played a more important role. Where such societies were not in existence before the war they were often estab-

lished after the war at the initiative of the municipal administrations. Large industrial concerns also frequently made use of such associations to provide housing for their employees. In France, Belgium, Italy and Spain, on the other hand, the task of promoting residential building was entrusted to administrative bureaus or commissions, often of pre-war origin. These authorities acted as intermediaries between the state, which furnished the funds for subsidy and credit grants, and the private builders. In France, for example, the central organization is the Conseil Supérieur des Habitations à Bon Marché, which acts through local offices attached in the form of departments to provincial, local and municipal administrations. In Belgium the central organization is a government owned corporation organized in 1919 and known as the Société Nationale des Habitations à Bon Marché. Local and regional activities are in the hands of other corporations, with shares distributed among the state, the provinces, municipalities, welfare institutions and private groups. Such local corporations, with the participation of the central and local governments, credit institutions and public service societies, have also been organized in Germany in recent years.

Table IV, based in part upon estimates, shows that in the post-war period non-private building was responsible for fully one fourth of all new construction. It must also be borne in mind that private enterprise in many countries was able to undertake building projects only because it received subsidies from public funds; this was the case wherever an adjustment of rentals in old buildings to the general price level was perma-

TABLE IV
POST-WAR BUILDING ACTIVITY BY VARIOUS BODIES IN EUROPE

| COUNTRY | AREA COVERED | PERIOD COVERED | PERCENTAGE OF DWELLINGS ERECTED BY | | |

nently prevented. Nor would unaided private building of small dwellings have been possible even without the continuation of rent restrictions in those countries where the shortage of capital was reflected in an extraordinary rise of interest rates. In pre-war Germany, for example, the cost of erecting a worker's dwelling was some 6000 marks; the annual rent amounted to 400 marks, which yielded 5 percent on the invested capital and left about 100 marks for maintenance and management. But in the post-war period following the stabilization of the currency the capital cost of a similar dwelling amounted to about 10,500 marks, while the interest rate averaged 10 percent; the rent called for was thus about 1200 marks, including maintenance and management, which was obviously far beyond the worker's budget.

The problem of obtaining public funds to finance building was solved differently in the various countries. In Great Britain, for example, such funds were provided out of the current budget. In some countries special taxes were introduced, levied in many cases on the permitted increase in rentals in old houses. In others public loans were floated either by the state itself or, as in Belgium, by a government owned corporation. In this way most countries succeeded in providing large sums of money for housing construction. The manner in which these public funds were actually made available differed. The simplest method involved the erection of dwellings by a public body, usually a municipality. This course was commonly followed only at the beginning of the post-war period to meet the most urgent needs, as experience has shown it lacks safeguards against the uneconomic use of capital. In Russia and in the city of Vienna this procedure was employed as a matter of principle. Somewhat related to this system was that of giving lump sum subsidies to private builders to cover that portion of the invested capital which could not earn interest and be amortized on the basis of the expected rental income of the house; the amount of subsidy was regulated according to the cost of construction or the type of dwelling. This method was used in England, Germany and elsewhere during the first post-war years but was usually abandoned because it led to the wasting of public funds. A variant of this system was employed in Belgium, where building cooperatives erecting one-family houses were given grants to facilitate the disposal of such houses. Another form of subsidy was the guaranty to builders of annual payments for more or

less lengthy periods in order to cover deficiencies in rental incomes. This type of grant was used chiefly in England during the first period of housing aid from 1919 to 1921 and in modified form in the legislation of 1923 and 1924. The effectiveness of such assistance depends upon a careful adjustment of grants and upon the availability of funds in the private capital market for building purposes. Elsewhere, particularly in France and Belgium, the state borrowed in the market for the purpose of providing private builders and public service societies with funds on reasonable terms; this was calculated to insure a permanent reduction in rents. In Czechoslovakia and Austria (outside of Vienna) the provision of loan funds on advantageous terms was assured by a state guaranty of the amortization and interest charges on loans made to private builders; such guaranty was secured by a portion of the rental income. Finally, where the private capital market was not strong enough to supply the necessary funds, it devolved upon the state to do so directly; since the terms on which such public loans were granted were more favorable than those ordinarily obtained from private sources, the differential amounted in practise to a subsidy. In many countries on the continent, notably Germany and Austria, the interest charge on such subsidy loans was much lower (1 to 2 percent) than the prevailing rate on prime mortgage loans (8 to 10 percent).

The task of furnishing large amounts of capital for housing construction was also assumed by special institutions, such as the building societies in Great Britain and the so-called building savings banks (*Bausparkassen*) first instituted in Germany after 1924. The credit societies found in the Latin countries also played a significant role; they obtained capital for building loans in some cases out of public funds and in others by their own bond issues. Still a third type is represented by the housing banks in the northern countries (Norway, Sweden, Finland); their loans are guaranteed by the state and at times they obtain direct financial assistance from the government.

Other financial measures intended to encourage residential building involved the grant of tax exemptions; those ordinarily allowed to the public service societies were exceptionally liberal. In the Latin countries, where the grant of direct aid was usually reserved for such groups alone, tax exemptions constituted the most important aid to the private builders.

In central Europe (Germany, Austria and

Czechoslovakia) and partly also in the Netherlands and Great Britain the public authorities sought to encourage building by providing house sites under very advantageous conditions. A German survey covering 173 municipalities shows that in 92 cities about two thirds of the total land used for housing construction during the period from 1919 to 1926 was furnished by the municipal administrations, as a rule to public service societies. To prevent the misuse of such lands for speculative purposes the public authorities forbade their resale or reserved the right of repurchase or consented to allocate them to builders only under a lease. In the Latin countries the state and the municipalities pursued this policy of land grants only on a small scale.

In most countries strict regulation and supervision of construction went hand in hand with public aid. Careful supervision was necessary to assure the economical employment of the public funds, the maintenance of adequate health and sanitation standards and finally the occupancy of these subsidized dwellings by the working classes for whom they were intended. In many cases therefore the maximum allowable costs for construction were fixed in advance, as were the maximum number of rooms, the maximum volume per room and the maximum proportion of area to be covered by the building. As a rule rent was also fixed and the contracts were so framed as to prevent unjustifiable profits upon the sale of the house. Real advances in physical comforts were thus achieved: toilets, bathing facilities, modern lighting and heating equipment and scientifically planned kitchen layouts became increasingly common in the European dwelling even of the cheapest kind. On the other hand, the number of rooms to a flat was reduced. Private construction was profoundly affected by this evolution; in many countries large flats built before the war remain unoccupied. Although the process is not yet completed, it is apparent that real changes have taken place in city and neighborhood layouts and in the grouping of houses as well as in the principles governing their design and equipment.

The effectiveness of the attempts to overcome the housing shortage in the post-war period differed considerably from country to country. In Great Britain in the first decade of the century no more than 130,000 dwellings were erected annually even in the years of the greatest building activity; in the years immediately preceding the war the total was only about 60,000 annually. Yet during the period from 1919 to 1929 the

number of dwellings constructed annually averaged almost 150,000; in the years 1926, 1927 and 1929 it reached more than 200,000; thus almost 1,600,000 dwellings were erected in the entire period, among them 600,000 by local authorities and 425,000 by subsidized private enterprise. This policy of subsidies effected a permanent annual burden on the Treasury alone, amounting in 1928 to £3,800,000. On March 31, 1930, the loans floated by the local authorities for the financing of their own building schemes totaled £400,000,000. After the most acute phase of the housing shortage had been dealt with British housing policy concentrated upon eliminating slums in industrial cities and raising standards in rural districts.

The Netherlands succeeded to a large extent in overcoming its housing shortage; building from 1921 to 1929 resulted in an estimated excess of 93,000 dwellings over the number required by population growth. This construction was largely the work of private enterprise. Following the restriction of the policy of public aid houses erected exclusively with private funds required a greater rent expenditure than the average worker's budget could afford.

In Switzerland there was never a serious housing shortage. Up to 1926, when the tenant protection ordinances were repealed, the republic had contributed, particularly to public service societies, about 32,500,000 francs to subsidize building, while 11,200,000 francs were provided as loans. In addition similar amounts were provided by the several cantons.

In Sweden also the housing shortage was adequately overcome. After 1920 there was employed a system of public credit grants, the extent of which diminished with the expansion of private enterprise. In Denmark public and especially non-profit housing construction was much more important than in Sweden. In this small country 64,000 dwellings were erected in a few years (up to 1927), more than half with the aid of the state and the municipalities. In Norway conditions were much worse despite the promotion of building by the state and by municipalities. Building by private enterprise has been comparatively small; because of the high building costs it has been impossible to erect dwellings to rent at a sum within the means of the average worker.

In Italy it was only after the stabilization of the lira that housing construction revived sufficiently to take care of current needs. Non-profit building was guaranteed the necessary

credits at easy terms. Compared with the pre-war period considerable progress was made in the size and sanitary equipment of small dwellings, but the complaint was frequently voiced that the rents were so high even in the houses constructed with government aid as to require about 23 percent of the worker's income.

France had to meet not only the problem of general housing but the task of organizing the construction of new dwellings in the regions devastated by the war. In the war zones almost 1,500,000 dwellings, some of them well planned and modern in design, were erected between 1920 and 1928. The campaign against the general housing shortage began, however, only after the stabilization of the currency. It was carried on with the aid of public credits and direct subsidies by the communes and by the public service corporations. Since statistical data are not available it cannot be determined how far the estimated deficit of 500,000 dwellings has been eliminated. Belgium had not succeeded in overcoming its housing shortage even as late as 1931. Only about 76,000 dwellings, erected between 1919 and 1929 with the aid of public funds, were available for the poorer classes, while their requirements actually called for about 130,000 new dwellings.

In Germany following the stabilization of the currency in 1924 the achievements in housing construction were quite extraordinary. Of the dwellings built in 1928 and 1929 in cities with more than 50,000 inhabitants 78 percent had been made possible by some form of state aid. During the years 1924 to 1930 no less than 16,700,000 marks was invested in housing construction. Approximately half this sum came from public funds, largely from the special house rent tax (*Hauszinssteuer*), and was advanced to builders in the form of mortgage loans at low interest rates. Building increased rapidly following 1924, the net increase totaling some 1,400,000 dwellings. More than 300,000 dwellings were erected annually after 1927, while the housing requirement for the natural increase of population was officially estimated at 225,000 dwellings. An endeavor was made to avoid the multistory mass tenement by the selection of new types; and compared to the pre-war period extraordinary improvements were achieved in the sanitary standards of the new dwellings.

Despite the subsidies from public funds the rentals required in new houses were extremely high. A typical worker's flat in Berlin, the average cost of which was 10,000 marks (including

land) in 1929, may serve as an example. The normal cost of financing, allowing for a cheap municipal mortgage and two mortgages from private sources at interest rates from 10 to 13 percent, amounts to about 640 marks per annum. To this is to be added a return on the owner's equity and an allowance for maintenance and management cost. For this reason the monthly rent in Berlin in 1930 for a newly erected two-room dwelling was 60 to 65 marks and for three-room flats 84 marks, while the average monthly wage of the skilled worker was 226 marks and of the unskilled worker 175 marks. Although the worker occupying an old dwelling spent but 12 percent of his income for rent, the occupant of a new dwelling—which, it is true, was much better equipped—was called upon to make an expenditure of 34 to 36 percent. Because the new dwellings were really not suited to the purchasing power of those classes of the population for whom they were intended, builders were compelled to resort to much cheaper types of flats as well as to alter the system of financing. This development was interrupted by the onset of the crisis in 1930 before slums had been eliminated in the big cities, evil housing conditions of the rural workers abolished or the problem of housing large families solved.

In Czechoslovakia political conflicts retarded the formulation of a governmental housing policy. Some 140,000 dwellings were constructed during the years 1920 to 1929 in cities with more than 10,000 inhabitants, but a survey of these cities made at the end of 1929 indicated a shortage of more than 64,700 dwellings. The need for housing was still therefore very great; no less than 17 percent of all families in the five larger cities took in boarders.

Housing conditions were very deplorable in Poland. In 1927 it was officially estimated that for the entire country there was a shortage of about 1,000,000 dwellings (as compared with existing totals of 1,300,000 in the cities and 3,500,000 in the rural districts). Almost half of all urban living quarters were overcrowded. Because of lack of funds several building cooperatives have been compelled recently to construct flats for workers containing merely a living room, kitchen and a side room with no window. The situation was not much better in the cities of Hungary or in those of the Balkan countries.

In the years 1930 and 1931 the depression brought about a serious interruption in building and in the development of housing policies.

Construction stopped almost everywhere, especially where it depended upon public aid; thus residential building failed to function as a stabilizing agency which would smooth out the cyclical fluctuations in business and contribute toward a revival of general economic activity. In many countries doubts were cast upon the effectiveness of the housing policy followed during the post-war decade. It was pointed out that the retention of rent restrictions for old dwellings resulted in an economically irrational distribution of tenants and created a false impression of housing needs. In some quarters it was insisted that it had been unwise to extend vigorous support to housing construction in a period of relatively high building costs, especially since the rents required by the new houses were too high for the worker's budget. It was also demanded that much cheaper and simpler types of housing be selected and that elaborate improvements in housing standards be dispensed with temporarily. The validity of all these objections, however, cannot at present be gauged effectively.

The future of housing policies must depend necessarily upon conditions of business, shifts in income distribution and population trends. Yet there can be no doubt that as a result of post-war developments the provision of adequate hygienically equipped dwellings for the poorer classes has become a permanent object of government and municipal policy in most European countries. Rent laws and the organization of building enterprise have undergone such profound changes that the ruthless exploitation of poorer tenants by builders and house owners has, it seems, become a thing of the past. The new types of settlement, the technical improvements, the innovations in housing construction and in the character of dwellings and materials—all that is implied in the phrase rationalization of housing—represent progress of a very real sort, the full benefits of which will become apparent only after the present crisis has passed.

KARL PRIBRAM

UNITED STATES. Differences between housing conditions in Europe and the United States are superficial. Differences between European and American methods of dealing with them are profound. Some of these differences are due to constitutional limitations on the functions of the American national government, others to prevailing social and economic theories.

The distinction between restrictive and constructive measures to improve housing may be

said to sum up the contrasting points of view prevalent in the United States and in Europe. The first is the predominant characteristic of American policy. Restrictive or regulatory measures, involving an exercise of the police power in the interests of public health, morals, safety or welfare and calling for adequate provisions for light, ventilation, repairs, cleanliness and protection against fire, are to be found in the ordinances of most cities and in the statutes of a number of states. Europe does not deviate markedly from this practise except that in most European countries legislation and administration are on a national basis as opposed to America's federalistic one. On the other hand, constructive measures for the purpose of bridging the economic gap between small incomes and the cost of adequate housing are a distinctly European development. In Europe housing for the masses of the population has come to be regarded as a public utility, as much the same sort of community responsibility as provisions for adequate water supply, sewage systems and street paving. Dwellings are necessities of modern life which are quite beyond the effective control of the average working class family.

Consonant with this attitude there have evolved in Europe the following public housing policies: the granting of state credits at low interest rates to individuals, public utility societies or municipalities; state or municipal building of houses for sale or for rent; tax exemption of new low rent houses for a limited term; and in the post-war period the granting of outright subsidies to non-profit building groups. Most Americans, on the other hand, cling to their pioneer philosophy as far as housing policy is concerned, believing that every self-supporting family can and should be housed as it is clothed and fed by its own unaided efforts. Whether this will prove to be a permanent attitude or only a passing stage in the social and economic evolution remains to be seen. It is important to note that in the United States the only measure of constructive housing which has been accorded any degree of recognition is that of granting tax exemptions to limited dividend housing companies which are renouncing a speculative profit.

The essential unity of the world wide housing problem is striking. Neither in the United States nor elsewhere does private enterprise unaided provide a satisfactory standard of housing for all or for even a majority of the people. In the United States new residential building is carried on for a comparatively small proportion of the

population. The remainder of the country's urban dwellers are compelled to fall back on the older, shabbier and inconveniently located houses formerly occupied by the well to do or to reside in slum areas. Here are located the oldest and worst houses, many of which are unfit for human habitation. Numerous housing surveys made during both the pre-war and the post-war periods show that nearly every community has its area of bad housing. In these districts overcrowding is the rule, rooms are dark or inadequately lighted, water and sanitary conveniences are lacking and dilapidation, excessive fire risks, basement and cellar dwellings are common.

A set of simple calculations may be set down to prove that only a small part—perhaps not more than one third—of American families have incomes large enough to permit the financing of new building or the occupation of new constructions. Fully one third of American families have incomes not in excess of \$1200 annually; a second third have incomes between \$1200 and \$2000; only the top third have incomes in excess of \$2000. In 1929 the average building cost (exclusive of land, promotion and financing costs) of one-family dwellings in 257 American cities was \$4915. But even if by eliminating all speculative profits the selling price could be fixed at \$4500, the purchase of such a house with the aid of a \$3000 first mortgage from a building and loan association would still require an outlay of \$585 annually for interest, amortization, taxes and the like. The rental of such a house with profit to the owner would not be appreciably less. It is plain that such an expenditure is above the proper limit of a family with an income of \$2000 or less.

Bad housing moreover is by no means limited to urban communities. Farm homes commonly lack conveniences. In a study of white farm families in eleven states made by the Department of Agriculture in 1926 it was indicated that 75 percent of the homes had no modern improvements whatever and that only 5 percent were completely modern. Federal Children's Bureau studies of rural housing in many parts of the United States have shown that an appalling proportion of white as well as Negro farm families live in one and two-room cabins, often with no sanitary conveniences of even the most primitive kind and sometimes without glass in the windows.

The basic circumstances determining housing standards in any nation are the size of family income, the proportion of income at various levels

that can be devoted to housing and the cost of residential building. Actual figures are relatively unimportant; the ratios existing among these three factors are the important considerations. It has already been noted that low income levels compel the greater part of the American population to live in old or slum houses. As for rent, it has been accepted in the United States that 20 percent of income is a normal proportion to devote to this purpose. At the health and decency level this is true. But where income is particularly low or the size of the family large, the proportion that must be spent for food increases at the expense first of savings and then of rent. For a considerable fraction of the population rent cannot in fact exceed 10 to 15 percent of income. In different sections of the country there are wide variations in building costs, but where the general level of wages and salaries and the cost of living are high building costs are also high. The general stability of the relationships between the cost of housing (both building cost and rent), cost of living and average labor income during the post-war period is shown in Table I.

TABLE I

INDEX NUMBERS OF BUILDING COST, RENT, COST OF LIVING AND LABOR INCOME IN THE UNITED STATES, 1918-30

| YEAR | AVERAGE BUILDING COST OF NEW DWELLING PER FAMILY | RENT | COST OF LIVING | AVERAGE WAGE AND SALARY INCOME PER EMPLOYEE |
|------|--|-------|----------------|---|
| 1918 | | 109.2 | 174.4 | 152 |
| 1919 | | 125.3 | 199.3 | 168 |
| 1920 | | 151.1 | 200.4 | 203 |
| 1921 | 100.0 | 161.4 | 174.3 | 169 |
| 1922 | 101.5 | 161.9 | 169.5 | 173 |
| 1923 | 104.6 | 166.5 | 173.2 | 192 |
| 1924 | 110.3 | 168.2 | 172.5 | 193 |
| 1925 | 113.1 | 167.1 | 177.9 | 199 |
| 1926 | 112.0 | 164.2 | 175.6 | 205* |
| 1927 | 112.7 | 160.2 | 172.0 | 208* |
| 1928 | 111.7 | 155.9 | 171.3 | |
| 1929 | 115.7 | 151.9 | 171.4 | |
| 1930 | 111.1 | 146.5 | 160.7 | |

* Preliminary figures.

Source: The average building cost index number, with 1921 as a base, is taken from *Monthly Labor Review*, vol. xxxii (1931) 944. The rent and general cost of living index numbers are those compiled by the United States Bureau of Labor Statistics with 1913 as a base. They are published in every issue of the *Monthly Labor Review*; those given here are for December of the corresponding years. The average wage and salary income index, with 1913 as a base, is taken from Conference on Unemployment, 1921, *Recent Economic Changes in the United States*, 2 vols. (New York 1929) vol. ii, p. 771.

While there was doubtless much inadequate and insanitary housing in colonial times, consciousness of the problem is barely a century old.

The first mention of bad housing as a cause of epidemics is found in a sanitary report written by Gerritt Forbes for New York City in 1834; and the second, which was more detailed and insistent, in a report of Dr. John H. Griscom, also for New York, in 1842. As in Europe, the growth of the housing problem came with the development of the factory system, which drew the workers to the towns, where no suitable housing accommodations awaited them. In American cities the steady stream of European immigration added to the crowding and pressure.

A series of investigations and reports followed Dr. Griscom's, but it was not until 1866 that the first tangible results appeared in New York with the creation of the city Health Department, followed in 1867 by the first tenement house law. This statute forbade cellar dwellings unless the ceiling was at least a foot above ground. It required also a water closet or privy vault for every twenty persons, city water in every house or yard and authorized the Health Department to enforce repairs. In new tenements there was to be a rear yard at least ten feet deep. It was not until 1879 that the building of rooms without windows was prohibited; from this requirement emerged the so-called dumb-bell tenement with its cheerless interior court.

A radical upward revision of the tenement house law occurred in 1901, following an elaborate investigation made by the Tenement House Commission appointed by the governor in 1900, of which Robert De Forest and Lawrence Veiller were respectively president and secretary. The revised law provided for a fairly high minimum standard in structure and sanitation for buildings to be erected or altered in the future, a much lower standard for buildings already in existence and a uniform standard of maintenance (cleanliness and repairs) for both old law and new law tenements. In new tenements the law banished the foul air shafts and required adequate open spaces in courts and rear yards, light and ventilation for each room and proper safeguards against fire. At the same time an amendment to the city charter created in New York City a Tenement House Department to administer the Tenement House Law.

That this statute, although a model law in its day, was merely restrictive and had no effect in speeding the demolition of existing obsolete structures is demonstrated by the following figures. According to the first report of the Tenement House Department there were 82,000 old law tenement houses in New York City when the

new law went into effect on January 1, 1902. The tenth report of the department shows that there were still 68,619 on January 1, 1930. A demolition of 13,381 houses in 28 years gives an average of less than 500 annually. At that rate it will still take more than 140 years for the last of them to go.

Here and there model tenements were built by philanthropists, notably those erected in Brooklyn between 1878 and 1890 by Alfred T. White. Other efforts were those of limited dividend companies, the chief examples of which were the Boston Cooperative Building Company organized in 1871, the City and Suburban Homes Company of New York in 1896 and the Washington Sanitary Improvement Company in 1897. The Octavia Hill Association of Philadelphia, whose work lay chiefly in the repair and management of old houses, was founded in 1896.

The period between the passage of the New York Tenement House Law in 1901 and the entrance of the United States into the World War was marked first by the enactment of tenement house laws in various parts of the country based on New York's statute and later by the adoption of broader codes known as housing laws, which dealt with all classes of dwellings. Typical examples of the earlier stage were the Pennsylvania tenement house law for second class cities (Pittsburgh and Scranton, 1903) and the New Jersey tenement house law of 1904. The best examples of the later period include the housing code of Minneapolis (1917) and the state laws of Michigan (1917) and Iowa (1919). Lawrence Veiller of New York furnished the leadership during this period and his model act served generally as a guide for progressive state legislation. It is interesting to note that during the 1920's not a single new restrictive housing law, state or local, was enacted in the United States. Yet this type of legislation had been the heart of the housing program of reformers in the preceding twenty years.

In 1918 the federal government found itself obliged to undertake the construction of houses and sometimes of whole new communities as part of its war industries program. The housing work of the Ordnance Department, which put up temporary structures, was unimportant. The Housing Division of the Shipping Board had an appropriation of \$75,000,000, and the United States Housing Corporation organized under the Department of Labor had \$100,000,000. Both employed excellent architects and town planners and built permanent modern dwellings

in well planned communities or subdivisions. The Armistice cut short their work, but the Shipping Board completed 8949 single family houses and 1119 flats in 23 communities at a cost of more than \$66,000,000. The Housing Corporation finished 5696 single family houses in 28 developments, which were ultimately sold to individual home seekers at an average price of \$3165 per house. Preference was given to occupying tenants and the terms were 10 percent cash and the balance by monthly instalments at 6 percent interest. While the government's entry into housing construction was purely a war measure indicating no change for peacetime policy, it had an important nation wide influence in setting higher standards for small house design and community layout than had previously prevailed. The experience also demonstrated that government housing could be produced and administered in the United States without scandal or extravagance.

On the other hand, government restrictions, high building costs and the appearance of new fields for capitalistic enterprise suspended private building during the war years 1917 and 1918 and kept it below normal during the three years following the Armistice. By 1921 there existed an acute housing shortage in the United States, which was conservatively estimated at 1,250,000 dwellings. With the close of 1922, however, the volume of residential building was already reaching the pre-war level (400,000 new dwellings annually); by 1928 the shortage had been wiped out in a numerical sense. Post-war building records (see Table II) show an important deviation from the pre-war emphasis on

one-family dwellings. During the 1920's apartment house construction was becoming increasingly significant until in 1928 it furnished more than one half of the new dwellings provided. During 1929 and 1930, however, the drift was in the opposite direction. The average building cost of new dwellings did not vary markedly from class to class or from year to year except for one-family houses, for which a tendency toward rising cost is apparent. Thus the average building cost for one-family houses was \$3972 in 1921, \$4134 in 1922, \$4915 in 1929 and \$4993 in 1930. The average cost for multifamily dwellings in the same years was \$4019, \$3880, \$4402 and \$3857.

While it lasted the post-war housing shortage resulted in congestion, the doubling up of families, occupancy of dwellings unfit for habitation and a general relaxation in standards of repair on the part of landlords and in law enforcement on the part of city authorities. Houses, however bad, could not be ordered vacated when there was literally nowhere for the tenants to go. The shortage also had the effect of raising rents and multiplying evictions. As a result a few jurisdictions—Maine, Massachusetts and Wisconsin during the war years; Washington, D. C., and New York after the war—enacted measures for temporary rent control. New York, to cite a single example, passed in 1920 a group of emergency rent laws forbidding evictions if the tenant set up the defense that the rent demanded was unreasonable and the agreement under which the landlord sought to recover it was oppressive. The municipal courts were ordered to find an increase of 25 percent in rent as presumptively unreasonable.

TABLE II

POPULATION, EXPENDITURE FOR NEW RESIDENTIAL BUILDINGS AND FAMILIES PROVIDED FOR IN DIFFERENT TYPES OF DWELLINGS IN 257 IDENTICAL CITIES WITH A POPULATION OF 25,000 AND OVER, 1921-30

| YEAR | POPULATION AS ESTIMATED BY THE CENSUS BUREAU | ESTIMATED EXPENDITURE FOR NEW RESIDENTIAL BUILDING (IN \$1000) | TOTAL NUMBER OF FAMILIES PROVIDED FOR | PERCENTAGE OF FAMILIES PROVIDED FOR IN | | |
|------|--|--|---------------------------------------|--|-----------------------|------------------------|
| | | | | ONE-FAMILY DWELLINGS | TWO-FAMILY DWELLINGS* | MULTIFAMILY DWELLINGS† |
| 1921 | 36,575,118 | 937,353 | 224,545 | 58.3 | 17.3 | 24.4 |
| 1922 | 37,511,516 | 1,612,353 | 377,305 | 47.5 | 21.3 | 31.2 |
| 1923 | 38,447,913 | 2,000,987 | 453,673 | 45.8 | 21.2 | 33.0 |
| 1924 | 39,384,311 | 2,070,277 | 442,919 | 47.6 | 21.5 | 30.9 |

able; the courts were empowered in a dispossession proceeding to fix the rents for a one-year term on the basis of a fair return on the whole value of the property. These laws were reenacted with modifications several times during the decade of the twenties and in their final form applied only to dwellings renting at \$10 a room per month or less in New York City. In 1929 the state legislature permitted the rent laws to lapse.

In an effort to stimulate new building tax exemption was resorted to in a few jurisdictions, the most important of which was New York City. Under an enabling act of 1920 adopted by the city in 1921 New York granted tax exemption until 1932 to a limit of \$5000 of building cost per one-family house, \$10,000 per two-family house and \$1000 per room in apartments, with a maximum of \$5000 per family unit, this to apply to all residential construction except hotels started before April, 1922 (later extended to 1924), and completed within two years. No control of rental or sales price was attempted nor were standards imposed beyond the requirements of the existing tenement house law and building code. This negative subsidy cost the taxpayers of New York City over the ten-year period close to \$200,000,000—a sum substantially exceeding the total capital expenditure for post-war housing (by public building or grants to private builders) of the London County Council. It is true that the device of tax exemption was an important factor in eliminating New York City's numerical housing shortage, for over the decade 1920-29 there was a net increase of 616,328 dwellings. But the new construction could be acquired or rented only by the top economic third of the population; this costly program of indirect subsidy in no way benefited the health and standards of living of the average working class family.

The progress in city planning achieved in recent years should have a favorable effect on the housing of the future. The part of the city plan most directly related to housing is zoning, which not only conserves residential neighborhoods from intrusions by business and industry but limits the height of buildings and requires open spaces about them in the interest of light and air. The phenomenal growth of zoning in the United States since 1916, when New York City's zoning ordinance was adopted, has taken place unfortunately at the expense of further development of restrictive housing legislation. While their fields overlap in the matter of light and air requirements, each does many things outside of

the other's sphere, and adequate protection would call for both. To January 1, 1931, there were 981 zoned communities in the United States, having an aggregate population of 46,000,000.

Suburban residence has increased with the use of automobile as well as rail and bus facilities. But if the lessons of regional planning are heeded, this tendency will be checked in the future by the systematic removal of industries and their workers from the crowded cities to new satellite towns planned from the start for healthful and convenient living. A rational distribution of population would lessen rather than increase the amount of daily going and coming between work place and home, which involves so much waste of time, money and vitality. Slum clearance, also logically a part of the city plan, is a familiar municipal function in Great Britain and the Netherlands and to a lesser extent in other European countries. It has been increasingly talked of in the United States in recent years but has thus far not been put into practise here.

Efforts to reduce the cost of housing in the interest of the lower income groups might be directed to any or all of the elements entering into the purchase price of a home. When a family buys a home, approximately half of the purchase price represents the house itself fairly evenly divided between materials and labor. Where land values are normal, about 20 percent represents the lot on an improved street and 30 percent goes for financing, sales cost and entrepreneur's profit. There has been much talk about doing for the working man's home through standardization of parts and quantity production what Henry Ford did for his models T and A; but the movement, as far as housing is concerned, has been so conspicuously lacking in result as to suggest that there is something faulty with the analogy.

In those European countries where cooperative housing is extensively practised by lower income groups it is made possible by long term, low interest bearing loans from government sources. In the United States cooperative housing has made its appearance, but because it has not the advantage of similar benefits it can offer no great advantages. Only in such cases as the small cooperative project in Milwaukee and the three cooperative companies which operate under the New York State Housing Law has any government aid been given cooperative housing in this country.

The experiences of European nations suggest that the part of the cost of a house concerned

with financing and profit is the one most susceptible of reduction. Because they successfully attack it at this point two recent American experiments stand out as promising most for future progress. One is an activity of the state of California, the other of the state of New York.

In the post-war period the general impulse of the states to express their gratitude to former service men followed the path of least resistance and expressed itself largely in the voting of small cash bonuses. California alone found a way to confer a more substantial benefit on her veterans by helping them to achieve home ownership and that without any expense to the taxpayers. California is one of the states whose constitution forbids the lending of its credit to any private individual or corporation. It cannot therefore finance the veteran in the purchase of his home, but it can and does buy the home for cash and sell it to him on a twenty-year payment plan requiring only a 5 percent down payment. The interest rate charged is also 5 percent. The monthly payment on a \$5000 home is \$33.10, covering principal and interest. At the date of the 1930 report of the Veteran's Welfare Board (established in 1921), 35,520 applications had been received for the purchase of homes or farms, of which 15,455 had been approved, including 7503 already built or in the process of building (by December 1, 1931, this figure had increased to 10,201). Up to that time bond issues to an aggregate amount of \$50,000,000 had been authorized by the California voters. But it is the veterans whose monthly instalments pay the interest on the bonds and redeem them at maturity. The average cost of homes purchased to 1930 was \$4742 and their quality is very high.

New York state, like California, has a constitutional bar against state housing loans. It has, however, been able to offer substantial encouragement to construction erected by limited dividend companies. In 1926 the legislature created the State Board of Housing with power to pass on the plans of limited dividend housing corporations. Those which receive its approval are exempted from state mortgage and franchise taxes. In the case of New York City, however, the only community so far to adopt the optional provisions of the act, buildings erected by an approved company prior to 1937 will be exempt from taxation for twenty years. This is the equivalent of a substantial subsidy; but because it is granted only to buildings complying with the very high standards required by the board (only 50 percent coverage of site, for instance, instead

of the 70 percent permitted by law) and because the rentals charged and profits made are strictly controlled, the results are socially useful and the volume of exempted building is not likely to become an appreciable burden to the taxpayers. Approved companies must furnish one third of the necessary capital and limit their return to 6 percent, the balance to be secured on first mortgage at 5 percent. Rents charged are not to exceed an average of \$12.50 per month per room (including heat) on Manhattan Island or \$11 elsewhere. For the public type of limited dividend companies the State Board may exercise the power of eminent domain to acquire a site. A member of the State Board serves on the directorate of every approved company. This insures careful business management and saves inexperienced groups from errors of judgment.

Three of the six companies so far approved under the law are cooperative organizations, one is a civic group and two are commercial corporations. These companies have built nine projects, representing an investment of \$9,000,000 and providing dwellings for 1700 families. Members of the Amalgamated Clothing Workers of America, who have been building cooperative projects in the Bronx since 1927, have demonstrated the usefulness of the law for workers with incomes of from \$30 to \$50 per week. This development has large sunny rooms looking out on beautiful gardens with fountains, pools and flower beds and is modern in every respect. The Amalgamated Dwellings on Grand Street built in 1930 show that equally fine apartments with almost equally beautiful gardens can be built on the lower East Side. The third cooperative group, the Farband, made up of members of the Jewish National Workers' Alliance was in 1928 the first to demonstrate that automatic elevators are an economic possibility in such houses if six stories high. Brooklyn Garden Apartments, Inc., has built on two sites which necessitated the clearance of shabby and definitely bad housing. The commercial developments are presumably a product of the financial depression. It is not likely that a proposal involving limited profits as well as regulated rents can interest commercial builders in periods of prosperity.

In conclusion it may be said that the progress inaugurated by the federal government's high standards in war housing has not been continued in the post-war decade. Most of the old houses which were below standard at the beginning of the decade were still in existence at the end and in a much worse state of repair. There was new

construction and the numerical housing shortage was eliminated. But only the top economic third of the country's population has benefited from the advances made by builders in the furnishing of added comforts and conveniences. So far as the greater proportion of the population is concerned and when its situation is compared with other working class groups throughout the world, the United States has lost ground. If Europe was a generation ahead of the United States in her attitude toward the housing problem in 1914, the distance is even greater at present.

HOUSING, COOPERATIVE. Cooperative housing means the organization of persons into a cooperative association and the creation and maintenance of domiciles by the association for the use of its members. In cooperative housing societies the members are shareholders; but title to the dwellings is owned by the group or association, which in turn rents the apartments or dwellings to the members. This rental is usually on a long term lease (commonly for ninety-nine years) and guarantees perpetuity of domicile to and control of the dwellings by the tenant members or their heirs. The making of profit either by sale of shares or by subletting is foreign to the purposes of the movement and in no true example of cooperative housing is the practise to be found.

In some associations the tenants do not constitute the whole of the owning organization. In Europe particularly housing societies are made up of persons desiring cooperative dwellings, but frequently such associations have more members than there are available flats or houses. Thus there always exists a spur to further housing expansion in the interests of the unaccommodated membership.

A cooperative housing society incorporates preferably under a cooperative law. The method of organization provides that each member shall have one vote and no more and that the enterprise shall not yield financial profits. A board of directors elected by the members is charged with the duty of administering the common business, such as the appointment of superintendents,

engineers, gardeners and other experts, the handling of finances and the like. The members of a housing society also often create committees to supervise such activities as education, recreation, playgrounds and gardens and in many cases to operate a bakery, restaurant, central kitchen, laundry, refrigerating plant, garage, hospital, clinic, dispensary, nursery or kindergarten. Not infrequently housing societies make joint arrangements for part time service of maids, cleaners, seamstresses and nurses.

It is customary practise to provide a reserve fund to be used for the purchase at par of shares of members who wish to resign, for all genuine cooperative housing societies permit the release of their members. In some societies the funds for the purchase of shares come from those members who are on the waiting list for dwellings. Societies in Germany allow the transfer of a member from one society to another, when circumstances compel him to move to another town.

There are certain minor and inessential deviations from the standards of cooperative organization already mentioned. A tenant member is sometimes under reasonable circumstances permitted to sublet his dwelling for a short period to a non-member tenant, but the approval of the board of directors is required. Such subletting may be at a profit to the renter member, especially when his furniture is also rented. In some associations, however, the member's profit is limited, usually to 5 or 6 percent, and all moneys in excess accrue to the treasury of the association.

The lease which a member receives from a cooperative housing society obligates him to pay a definite sum each month toward the meeting of fixed expenses. These are made up of two sets of items; namely, current running charges and capital charges. In the first are customarily to be found interest on share capital, bonds, mortgages and notes; taxes; fire and liability insurance; light and fuel; wages; repairs and supplies. In the second are to be found payments on the principal, amortization of mortgages and the building up of a depreciation fund. As the indebtedness of the society is paid off, the interest and amortization charges decrease with the result that the monthly "rentals" grow smaller.

Capital for the construction or purchase of cooperative housing is obtained by the sale of shares of the corporation to the members. The member pays in cash a sum equal to the cost of the dwelling to be occupied by him less the proportionate amount of money secured on

mortgage loan. If a dwelling house or apartment is to cost \$2500, the member subscribes for \$2500 of stock. But in the beginning he need pay in cash only the amount not supplied by the mortgage loan. Thus, if the mortgage is on the basis of 50 percent of the total cost, the subscribing member pays \$1250; if mortgages and loans covering 75 percent of the property are secured, the member's original payment is \$625. Members often borrow this money by putting up their stock as collateral. Some societies raise money by first, second and even third mortgages. A callable bond issue sold to members and friends is another method of securing capital, while preferred stock issues are sometimes resorted to in place of bonds.

The chief difficulty facing the cooperative housing movement is the raising of the initial capital. In this respect housing societies have fared best in Germany. Municipalities, states and the Reich have made twenty-year loans (without interest) to cooperative housing societies through the enactment of legislation applicable to "house construction for residence purposes only and not for sale or profit-making rental." Also land grants have been made to housing cooperatives with the stipulation that ownership of such lands is to rest in the society if at the end of twenty years the property has been used for residence purposes by the owners only.

In addition to the activities of the simple housing society, which concerns itself purely with housing and which is financed and administered by the tenant members, there is to be found a growing practise on the part of European consumers' cooperative societies to engage also in housing. For example, the Konsum-, Bau- und Sparverein of Hamburg, Germany, which has a membership of 150,000 persons, in addition to operating a bakery, a meat packing plant, canning works, a mineral water bottling establishment and food, furniture and tin ware factories as well as banking and insurance enterprises, owns ninety-one building sites containing over 1480 flats. These dwellings are rented to its members, the society acting as landlord. As landlord, however, the society's properties are controlled not only by the members who occupy its apartments but also by the 148,800 who live elsewhere. In this respect such a society differs materially from the pure housing association. The distributing function developed first; the housing function followed and was financed by the surplus savings accumulated in the other enter-

prises. It is to be noted that the tenant members are organized into a housing department for the local control and administration of the dwellings which they occupy.

In the United States not many purely cooperative commodity distributing societies are to be found. On the other hand, some cooperative housing societies have met with real success. In due time some of these have learned that it is possible to engage effectively in the distribution of commodities, once the housing venture has been successfully launched. The Amalgamated Cooperative Apartments of New York City is an excellent example of this form of development. Beginning with the operation of nearly two city blocks of buildings, containing 503 apartments, the members of this group turned to the distribution of commodities and before long were maintaining their own grocery stores, supplying their own milk and conducting a furniture department, dental and medical clinics, a library, a forum and a farm.

Most cooperative housing is developed by cooperative housing societies. In Germany, where this type of cooperative has flourished, the number of societies has increased from 1342 in 1914 to 4128 in 1927. Receiving subsidies and credit assistance from governmental sources the housing cooperatives, because they were called upon to raise but a small proportion of the needed funds themselves, have been able to embark on extensive building projects. Thus by 1927 the societies of the *Hauptverband Deutscher Baugenossenschaften*, a federation of 2525 societies with a membership of 633,629 and a share capital of 214,000,000 marks, were responsible for the erection of 273,230 dwellings, or accommodations for approximately 40 percent of their combined membership.

In the suburbs of most German cities are to be found extensive cooperative housing developments. The apartment houses at Neukölln in Berlin are fine examples of pure cooperative housing. Britz, another suburb, has some three hundred charming stucco covered, tile roofed houses with gardens and playgrounds, all occupied by working people. Nuremberg offers particularly attractive examples of cooperative houses, which far surpass in beauty, conveniences and size workers' dwellings of other industrial countries. Garten Stadt Nürnberg is a cooperative village of some three hundred detached houses, where each dwelling has a flower garden in front and a vegetable garden in the rear; the whole development is laid out in compliance

with modern town planning and landscape gardening.

In Denmark one out of every five persons in the population lives in a house erected by the municipalities or the cooperatives. Copenhagen possesses excellent examples of cooperative apartment houses, each built around a court, each one occupying a city block and housing approximately 215 families. The *Kooperative Bauvereinigung der Arbeiter* of Copenhagen has over six thousand members and has built over four thousand apartments in eighteen different groups of buildings. Priestfields, a suburb of Copenhagen, is a cooperative village which has on the colony grounds stores for groceries, meats, hardware and house furnishings. The Danish cooperative housing societies are federated to form a central organization and operate factories and plants for the production of windows and doors, pipe, tile, brick, paint and cement. Switzerland has highly successful cooperative housing developments. The village of Freidorf near Basel is an example of a completely cooperative community, in which the society owns not only the houses and land but the streets, park and central community buildings. Cooperative housing is well developed also in Austria, Switzerland, Norway and Sweden and national federations of societies are found in these countries.

Although the modern housing reform movement may be said to have had its beginning in England, cooperative housing has not been responsible for much construction here. It is to be noted, however, that evidences of progress in the post-war decade are not wanting. The number of cooperative housing societies increased from 246 in 1920 to 283 in 1928 and the membership from 11,021 to 25,030 persons. Similarly the share capital of these societies grew from £615,369 to £1,051,785 and the total value of rents from £336,715 to £677,367.

The first cooperative houses in the United States were built in Brooklyn, New York, in 1916, by Finnish cooperators. The movement has shown no great progress, in 1929 there being only forty-five cooperative housing societies in the country. Twenty-five societies reporting to the federal Bureau of Labor Statistics controlled, in all, property valued at \$8,000,000 and provided dwellings for 2300 families and 650 single persons. It was apparent that among these American societies there was marked deviation from sound cooperative practise. Of the twenty-five societies reporting twelve permitted sub-

letting and fourteen permitted their members to sell their apartments at a profit. Six societies were even allowing members to vote by shares instead of following the regular cooperative procedure of a single vote per member. Not more than nine of the societies were maintaining a policy of true cooperative housing.

Since the World War there have appeared in many American cities large scale projects called cooperative apartments which have nothing in common with the cooperative movement. These houses, the products of real estate and building exploitation and speculation, have been erected not for dwelling but for commercial purposes. Each apartment is in due time sold to an owner, who may or may not elect to be a tenant. Ownership is represented by possession of shares of stock in the whole house owning corporation and by lease of an apartment; but the sale of the stock and the transfer of the lease are permitted. Under these circumstances an apartment is on the market for sale, lease and transfer very much like any privately owned dwelling.

Some of these pseudo-cooperative houses place restrictions upon transfers, requiring either the approval of a board of directors or demanding that an apartment for sale or rent first be offered to the corporation holding title to the house. Indeed some corporations actually own a certain number of apartments in the house; these are rented at a figure above the cost price. In some instances the house has twice as many apartments as there are tenant owners and these constituting the corporation rent half of the apartments to non-stockholders. It is not uncommon for this type of exploitation of tenants to reach such proportions that the tenant owners are able to obtain their rents free.

HOUSSAYE, HENRY (1848-1911), French historian. Houssaye, who before turning to historical writing had gained a reputation as a brilliant, sophisticated essayist, as a student of antiquity and as a literary and art critic, is remembered primarily for his studies in praise of Napoleon. His four-volume series, *1814, 1815, Waterloo, la seconde abdication* (Paris 1888-1905), achieved by reason of its scholarly as well as literary merits unusual success. Having carefully combed in the preparation of this work contemporary memoirs, newspapers, police reports and writings of travelers, Houssaye was able to depict with a wealth of illustration the currents of popular feeling and agitation and to clarify the social atmosphere which enveloped the political actions of Napoleon and his ministers. The ardent patriotism of the author, who had served as an officer during the Franco-Prussian War, is reflected in the intensely emotional accounts of the defeats of 1814 and 1815 and in the unqualified sympathy with which he championed Napoleon's cause against his adversaries. Because of this strong prejudice in favor of Napoleon, Houssaye has been charged with being indifferent to the exhausted condition of France and to its great need for peace and liberty. But the historical value of the work as a whole is beyond question. It contributed greatly to the revival of the Napoleonic cult, which manifested itself so strongly in France between 1890 and 1900 but which shortly died out again.

HOWARD, GEORGE ELLIOTT (1849-1928), American historian and sociologist. Through his studies in history, political science and Roman law in Munich and Paris Howard became interested in social history, particularly in institutional history. In 1879 he became the first professor of history in the University of Nebraska. In spite of meager facilities he wrote his *An Introduction to the Local Constitutional History of the United States* (Baltimore 1889) and his "On the Development of the King's Peace" (in University of Nebraska, *Studies*, vol. i, no. 3, 1888-92, p. 235-99), works which led to his appointment to the faculty of the new Stanford University, where for ten years he did notable work in fostering creative research in institutional history. His devotion to the principle of academic freedom led him at great personal sac-

rificed to resign his professorship there as a protest against the dismissal of his colleague Edward A. Ross. He then devoted himself to his classic work, *A History of Matrimonial Institutions* (3 vols., Chicago 1904), which is an encyclopaedic record of the diversified forms, laws and practices of marriage existing among primitive and civilized peoples. Upon his return to the University of Nebraska as professor of international history and head of the department of political science and sociology he made many contributions to periodicals in the fields of modern English history and biography, social psychology and sociology. He believed education to be the most efficient instrument of social control and agency of democracy and internationalism, taught the potential equality of the sexes and races and decried race prejudice. He was a genuine liberal, lent encouragement to social welfare measures, publicly championed such causes as woman suffrage, prohibition and international peace and demonstrated that social theory need not atrophy the scholar's humanity or sense of concrete social reality.

ARTHUR J. TODD

J., in *American Journal of Sociology*, vol. xxxiv (1929) 693-99.

HOWARD, JOHN (1726-90), English social reformer. Howard was born in Hackney, London. He was the son of a wealthy upholstery and carpet merchant, and although he was educated in several private schools he always complained of the inadequacy of his training. His marked humanitarian interests were motivated by his religious outlook, which produced a stern, almost ascetic, reaction to life. He encouraged the institution of public sanitary measures, the erection of model dwellings and the improvement of educational methods. His most important work, however, was in prison reform. In 1773 as sheriff of Bedfordshire he was horrified by the abominable conditions prevailing in the jails, especially the filth, disease and jail fever. He was particularly shocked to find that many of the sufferers were obviously innocent men who had never been prosecuted or convicted but who could not pay the jail fee necessary to secure release. He made further investigations of British jails and prisons and as a result initiated and personally advocated the legislation

passed by the House of Commons in 1774, providing for the abolition of the fee system, the payment of a fixed salary to the jailer and the improvement of sanitary conditions in jails. Howard then devoted himself to a study of prison conditions abroad, made a more thorough study of English prisons and jails and published *The State of the Prisons in England and Wales, with Preliminary Observations and an Account of Some Foreign Prisons* (Warrington 1777; 4th ed. by John Aikin, 1792), which was much discussed by students of public affairs, criminal law and penal administration. He added two substantial appendices to the book after studying prison construction throughout Europe between 1778 and 1783. Howard next investigated the prison hulks and the hospital and quarantine ships, fruitful sources for the spread of the plague, and at the risk of his life traveled on a quarantine ship in the Mediterranean. He published the results of these inspections in *An Account of the Principal Lazarettos in Europe* (Warrington 1789). While in Russia studying prison conditions he contracted fever and died at Kherson.

Howard's works had a demonstrable influence upon the improvement of prisons in Europe and America. They inspired the model British prison erected at Wymondham in Norfolk by Sir Thomas Beevor in 1784 and the activities of the Philadelphia Society for Alleviating the Miseries of Public Prisons, the germinal source of prison reform in the United States.

HOWE, JOSEPH (1804-73), Canadian statesman. Howe first established a reputation as a Nova Scotian journalist and publisher who fostered an interest in native culture, native literature, local resources and political reform and vindicated the freedom of the press. In 1836 he

entered public life as a member of the Nova Scotian assembly and became the leading figure of the popular party. He gained public enthusiasm for the movement in behalf of responsible colonial government in the Maritime Provinces which coincided with a similar agitation in the Canadas. By his pamphlets and articles, which circulated in both the colonies and Great Britain, by his correspondence with influential persons and by his political tactics he contributed materially to the winning of the concessions from the home government which resulted in the establishment of the first responsible party government in the British colonies in Nova Scotia in 1848, without the bloodshed of the Canadian rebellions of 1837. During the struggle he provided a contribution to political philosophy not unworthy to stand by Durham's report in his four-letter reply (published in pamphlet form as *Responsible Government*, Halifax 1839; reprinted in Kennedy, W. P. M., *Documents of the Canadian Constitution*, Oxford 1918, p. 480-514) to Lord John Russell's speech of June 3, 1839, in which the latter conceded that the feelings of the colonials with respect to their affairs must be consulted but refused with hairsplitting dialectic to grant responsible government. Howe shattered Russell's position with penetrating logic and realism. He exposed the failures of the old colonial system; and while he proposed to leave to the imperial Parliament the control of foreign affairs, naval and military forces and colonial trade with Great Britain and general supervision analogous to that over an incorporated town, he demanded for the colonies full control over their local affairs as a guaranty of majority rule and imperial unity. In a period of discouragement he was an ardent defender of imperial as well as of greater colonial unity. On behalf of these ideals he labored with some success in the field of transportation. Nevertheless, he was opposed for a time to the federation of 1867. On the offer of better financial terms for Nova Scotia he entered the federal cabinet in 1869, but secession sentiment persisted in the province for a generation.

HOWE, JULIA WARD (1819-1910), American writer, social reformer and feminist. Mrs. Howe mirrored to an extraordinary degree in the course of her long life the evolution of bourgeois culture in the United States. The scope of her interests progressed from the maintenance of the union, which her forbears, the Wards and the Greenes, the Cutlers and the Marions, had shared in building, to the organization of women for an extension of citizen equalities; from inherited military traditions, stimulated by the second American revolution, to the possibilities of a peaceful arbitrament of disputes, causing her after writing the celebrated martial paean for the army of the northern industrialists—*The Battle Hymn of the Republic*—to summon the women of the world to an antimilitarist crusade at the outbreak of the Franco-Prussian War; from piety to philosophic speculation; from self-improvement associated with the arts, languages and letters to self-expression in many fields, including poetry, drama, travel tales, biography, treatise, tract and memoir.

From New York society of an exclusive sort, as the daughter of Samuel Ward—opponent of Jackson and the planters, proud of his private art gallery, library and poetic wife, Julia Rush Cutler—Julia Ward moved to Boston following her marriage to Dr. Samuel Gridley Howe, an internationally known humanitarian, and became one of the circle of New England intellectuals for which the middle period of the nineteenth century was famous. She allied herself with the Unitarians, tried to popularize metaphysics, discovered certain social realities, wrote *Passion Flowers* (Boston 1854) and *Words for the Hour* (Boston 1857) in response to the fateful European upheavals of the late 1840's and the impending domestic civil conflict, came into contact with social work through her husband's activities, mothered five children and was a popular *salonnière*. Her widowhood of thirty-four years was spent largely in association with women, organizing clubs, advocating woman suffrage and appealing to mothers to stop the child sacrifice caused by warfare.

MARY R. BEARD

Important works: The most complete collection of her poems is entitled *From Sunset Ridge, Poems Old and New* (Boston 1898). Selections from her speeches and essays are found in *Julia Ward Howe and the Woman Suffrage Movement*, ed. by F. H. Hall (Boston 1913); and selections from her journals in *The Walk with God*, ed. by L. E. Richards (New York 1919). Her biographical writing comprised sketches of her husband, *Memoir of Dr. Samuel Gridley Howe* (Boston

1876), *Margaret Fuller* (Boston 1883), and *Sketches of Representative Women of New England* (Boston 1904). See also her *Reminiscences 1819-1899* (Boston 1899). Consult: Richards, Laura E., Elliot, Maude H., and Hall, Florence H., *Julia Ward Howe*, 2 vols. (Boston 1915); Adams E. C., and Forster, W. D., *Heroines of Modern Progress* (New York 1913) p. 178-214; Harvey, L. A., in *Stratford Journal*, vol. iv (1919) 300-11; Townsend, H. A., *Reminiscences of Famous Women* (Buffalo 1916) p. 15-22; Mead, Edwin Doak, *Julia Ward Howe's Peace Crusade* (pamphlet, Boston 1910).

HOWE, SAMUEL GRIDLEY (1801-76), social welfare pioneer. Howe was one of the group of distinguished social pioneers in Boston before the Civil War. On graduating from Harvard Medical School he fought for Greece during its war for independence, became surgeon general of the Greek fleet and organized relief work until 1830. At the suggestion of his friend Dr. Fisher after study abroad he established in 1832 one of the first American schools for the blind, the Perkins Institution and Massachusetts School for the Blind, of which his annual reports (Boston 1833-75) form a valuable record. His success with Laura Bridgman, a blind, deaf and dumb child of seven, served as a precedent for the education of Helen Keller. His work, including improvements in printing, attracted national attention and he visited seventeen state legislatures, urging provision for the education of the blind. He advocated the use of the method of articulation in schools for the deaf at a time when only the finger alphabet and sign language were in use in the United States. He undertook the education of the feeble-minded and prepared the first American state paper on this subject (*Report Made to the Legislature of Massachusetts, upon Idiocy*, Boston 1848), which led to the establishment of the Massachusetts School for the Feeble-minded. He worked for the better care of the insane and as a member of the Massachusetts legislature presented the first legislative memorial of Dorothea Dix in 1843. He advocated prison reform and new methods of dealing with juvenile delinquents. The first state board of charities was organized in Massachusetts in 1863 as a result of his suggestions to the governor; at the close of the war he became chairman of the board. His annual reports are valuable state documents. He was one of the founders of the science of public welfare administration.

Dr. Howe actively opposed slavery. With his wife, Julia Ward Howe, he edited the *Commonwealth*. He ran for Congress in 1845 as a "conscience Whig," was chairman of the Vigilance Committee organized in 1846, went out to

"bleeding Kansas" with supplies in 1856 and was a supporter of John Brown. During the Civil War he was a member of the Sanitary Commission and he served as chairman of the United States Freedmen's Inquiry Commission. His later activities included trips to Crete in 1867 to direct relief during the rebellion and to Santa Domingo, where he advised annexation and organized a land reform company.

HOWELL, GEORGE (1833-1910), British trade union leader. Howell began working on a farm at the age of eight. He became a bricklayer and while still young joined the Chartist movement. He first achieved prominence in the great London strike for a nine-hour day in the building trades in 1859. Although the strike failed, the new trade unionism, seeking practical and attainable ends, was strengthened. Among the more important results of the strike were the formation of the London Trades Council, of which Howell was for a time secretary, and the transformation of the paid agitator into the trained official. A group of such officials, known as the Junta, with Howell as a prominent member, directed trade union affairs and succeeded in strengthening the foundations of the unions and removing the worst of the legal disabilities that hampered their full development.

With the passage of the second Reform Act in 1867 Howell endeavored to enter Parliament. After three unsuccessful attempts he was elected in 1886 as a Liberal for Bethnal Green, a London working class constituency, and retained his seat until 1895. He strenuously opposed the formation of an independent labor party, thus incurring the bitter hostility of the younger trade union leaders. In Parliament, however, Howell championed every cause for the extension of liberty and the welfare of the workers. He had a ready pen, had read widely and wrote and spoke with authority on all labor questions.

surance (London 1880); *Trade Unionism, New and Old* (London 1891, 4th ed. 1907); *Trade Union Law and Cases* (London 1901), written in collaboration with Herman Cohen; *Labour Legislation, Labour Movements and Labour Leaders* (London 1902; 2nd ed., 2 vols., 1905).

HOWITT, ALFRED WILLIAM (1830-1908), Australian anthropologist. Howitt was born in Nottingham, England, the son of William and Mary Howitt, both of whom were popular English authors. After studying in Germany and at University College, London, he went to Australia in 1853. He became interested in native life about 1863, when he was appointed warden of the gold fields in Gippsland, southeast Victoria. His first systematic work was begun in 1873 when Lorimer Fison, seeking information on kinship terms for Lewis Henry Morgan, appealed through the press for information concerning the Australian aborigines. With Fison he published the important book *Kamilaroi and Kurnai* (Melbourne 1880), to which he contributed the chapters on the Kurnai. His theoretical conclusions supported Morgan in the acrimonious controversies with McLennan and Lubbock, attacking their contentions that the kinship terms were merely terms of address and that exogamy arose because of female infanticide and marriage by capture. He conceived as Morgan did that exogamy arose from the deliberate intention of the natives to avoid marriage of close relatives, although actually exogamy regulations do not perform this function effectively. He also criticized the theory of degeneration as an explanation of primitive culture. Characteristic of his period, he formulated an evolutionary scheme in which he held that Australian aborigines had progressed from an "undivided commune," in which more or less promiscuous cohabitation existed, through a "segmented commune," consisting of two or more exogamous intermarrying groups, to individual marriage, in which traces of communal rights still survived.

Howitt persisted in this theoretical position in many contributions to periodicals, some of which were published jointly with Fison, and in his classic work *Native Tribes of South-east Australia* (London 1904), in which he embodied the vast materials derived from his lifelong ethnological researches. In it he also suggested a positive correlation between the progress of the culture of the different Australian tribes and the degree of rainfall in the regions in which they lived and expressed agreement with Spencer,

Gillen and Frazer that the primary function of totemistic groups was to insure a food supply by magical ceremonies.

BERNHARD J. STERN

Consult: Stern, Bernhard J., "Selections from the Letters of Lorimer Fison and A. W. Howitt to Lewis Henry Morgan" in *American Anthropologist*, n.s., vol. xxxii (1930) 257-79, 419-53, and *Lewis Henry Morgan, Social Evolutionist* (Chicago 1931); Frazer, J. G., "Howitt and Fison" in *Folk-lore*, vol. xx (1909) 144-80; Lang, A., in *Man*, vol. viii (1908) 85-86.

HOXIE, ROBERT FRANKLIN (1868-1916), American economist. The greater part of Hoxie's study and the second of his two decades of teaching were done at the University of Chicago. Influenced in turn by the economic doctrines of Laughlin and Fetter and still more powerfully by those of Veblen, and by the work of C. H. Cooley and G. H. Mead in allied fields, Hoxie attempted revisions of economic theory that would do greater justice to the complexity and endless changes of industrial life (see especially "On the Empirical Method of Economic Instruction" in *Journal of Political Economy*, vol. ix, 1901, p. 481-526). It was in the study of American trade unionism, however, that he found the major opportunity to use the genetic method toward which his thought had turned. True to his early description of economic forces as "not only manifold but kaleidoscopic," he insisted that unionism was not unitary but diverse in character. The resulting analysis of unions into "functional types" (*Trade Unionism in the United States*, ed. by L. B. Hoxie and Nathan Fine, New York 1917, 2nd ed. 1923) and the demonstration that scientific management and "business unionism" were incompatible as then conducted (*Scientific Management and Labor*, New York 1915) are among the more important contributions in his studies of labor. They are marked by a "toughmindedness" unusual in the field and by an unremitting attempt to penetrate to the causes of fundamental differences in preconceptions and prejudices.

Hoxie's publications measure neither his full powers nor his influence. Throughout his life he was handicapped by ill health and a habit of merciless self-criticism. His labor studies, although they showed results that could not have been secured without innumerable hours of field investigation, give little picture of the processes by which he drew inferences from the unconscious admissions of the employers and unionists he knew so well. A very large part of his best and most influential work, moreover, found only oral

expression in what must have been very nearly the most realistic of American classrooms. Yet enough remains to make clear that Hoxie possessed the keenest and most rigorous mind that has ever worked upon the problems of American labor organization.

HUBE, ROMUALD (1803-90), Polish jurist. Hube was professor of law at first in Warsaw and later at St. Petersburg. In 1833 he was made a member of Speransky's commission for the revision of the laws of the Russian part of Poland. For it he prepared a draft of the criminal code and in 1835 a draft of the code of criminal procedure. He was co-author of the Russian criminal code of 1845, which was extended with some modifications to Poland in 1847. From 1856 to 1861 he was chairman of the codification commission for Russian Poland.

The German historical school, predominant at that time, influenced Hube in many directions. Thus he felt that for the dogmatic treatment of existing law legal history was indispensable. Likewise in the spirit of Savigny was his attitude toward Roman law as a living law; also toward the derogatory force of customary law and toward the relation between theory and practise. Nevertheless, he expressed himself decisively against regarding custom as the single source of law. Hube rightly estimated highly for every period in history the significance of a conscious legislative activity, and thus his own was not inconsistent with his premises. Indeed he was justified in all his departures from the doctrines of Savigny. In his conception of the criminal law Hube was entirely in favor of unconditional retributive punishment in the spirit of Hegel. In conformity with this point of view was his insistence upon the unconditional subsumption of each criminal act under the criminal law. This view of law as unconditional norm was in direct contradiction to his position on Roman law; he valued it highly as a historically conditioned and therefore relative living law.

Hube's legal historical researches stand in close relation to his concepts of legal theory. They have as their subject old Polish, former

Slavic and western European law. Almost all are basic, original researches whose methods have been followed in the study of Polish history. They still retain their value.

WLADISLAUS MALINIAK

Works: *Pisma Romualda Hubego*, with a biographical-critical sketch by K. Dunin, 2 vols. (Warsaw 1905).

Consult: Doreste, Rodolphe, in *Nouvelle revue historique de droit français et étranger*, 3rd ser., vol. xiv (1890) 941-42.

HUBER, EUGEN (1849-1923), Swiss jurist. Huber studied law at the universities of Zurich and Berlin, continued his studies in Italy, France and England and received the degree of doctor juris in 1872. In 1873 he became *Privatdocent* at Berne and later editor in chief of the *Neue Züricher Zeitung*. He was forced to resign his editorship in 1877 because of political controversies. In 1880 he was appointed a professor of civil law and legal history at Basel University. Subsequently he taught at Halle and finally at Berne, where he remained until his death. From 1903 to 1911 he was a member of the Swiss National Council.

Huber was the author of scholarly works on mediaeval German law, especially on its dotal system, its law of inheritance and its law of possession. On the last subject he wrote his excellent study *Die Bedeutung der Gewere im deutschen Sachenrecht* (Berne 1894). Influenced by his friendship with the legal philosopher Rudolf Stammler, he wrote toward the end of his life several books on the philosophy of law, which are excellent in their combination of dogma and practicality. His chief work in this field is *Recht und Rechtsverwirklichung* (Basel 1920).

He is best known, however, as the author of the famous Swiss civil code, which the government authorized him to draw up in 1892 (*Schweizerisches Zivilgesetzbuch vom 10. Dezember 1907*, Berne 1908; tr. by I. Williams, Oxford 1925). An excellent preparation for this notable task was the research which he did for his *System und Geschichte des schweizerischen Privatrechts* (4 vols., Basel 1886-93). The first three volumes of this standard work are a clear and systematic presentation of the civil law of the twenty-five Swiss cantons, while the fourth volume contains the history of Swiss private law from the time of the *Lex alemannorum* and the *Lex burgundiorum*. In 1900 he presented the first plan for the civil code; in 1904 he finished the official draft, which was adopted by the National Council

and the Council of the States in 1907 and put into effect in 1912. Before that date only the law of obligations had been codified. Huber's code was entirely his own work. It gave more weight to old German institutions and less to Roman law than did the German civil code of 1900; and it was not a mere unification of the laws of the cantons but rather a practical amalgamation of historical, social and ethical elements. Particular emphasis was given to the concept of the sanctity of the family. The Swiss code became a model for the Turkish civil code. After finishing the civil code Huber prepared to revise the Code of Obligations, a task which he was unable to complete and which was brought to an end by others.

EDUARD HIS

Consult: Mutzner, Paul, in *Zeitschrift für schweizerisches Recht*, vol. xlii (1924) 1-44, with bibliography of Huber's works; Stutz, Ulrich, in *Zeitschrift der Savigny-Stiftung für Rechtsgeschichte, Germanistische Abteilung*, vol. xlv (1924) xi-xxix.

HUBER, ULRICUS (1636-94), Dutch publicist and jurist. Huber became professor of history and elocution in 1657 and in 1665 professor of law at the University of Franeker. His reputation as a jurist and orator was such that he attracted to the university students not only from the various provinces of Holland but also from Germany, England, Scotland and elsewhere. In 1679 he became a member of the Provincial Court at Leeuwarden.

Among the Dutch writers of the seventeenth century Huber occupies a preeminent place. He was a prolific writer on historical, theological and philosophical subjects as well as on law and engaged on various occasions in polemics with theologians and fellow jurists. As a jurist he was equally eminent in Roman, public and Frisian law. Of his works on Roman law the most important are *Praelectiones juris civilis* (3 vols., Franeker 1689-1701; new ed. by Judocus Le Plat, Louvain 1766), *Digressiones justinianae* (Franeker 1671; 3rd ed. by Zacharias Huber, 1696) and *Eunomia romana* (ed. by Zacharias Huber, Franeker 1700; 2nd ed. Amsterdam 1724). His principal work on public law is his *De jure civitatis*, in which he developed general principles of public law as distinct from politics. From this work Rousseau derived part of his fundamental theory for his *Contrat social*. The work by which he is best known today in his native country is his *Hedendaegse rechtsgeleertheit, soo elders, als in Frieslandt gebruikelijk* (Leeuwarden 1686; 4th ed. by Zacharias Huber,

Amsterdam 1742), in which he set forth in the light of the decisions of the courts the private, constitutional, procedural and criminal law of ancient and modern Friesland.

In the United States and England Huber is known as the author of "De conflictu legum diversarum in diversis imperiis," which appeared in his *Praelectiones* (vol. ii, p. 24-30). In this brief treatise Huber reduced the basic principles of the science of private international law to a few axioms, which Story and Anglo-American courts in general readily accepted. Together with Paulus and Johannes Voet, Huber became a founder of the Dutch school, which school proclaimed "comity" to be the foundation upon which the rules of the conflict of laws were based.

ERNEST G. LORENZEN

Consult: Boeles, W. B. S., *Friesland's hoogeschool en het rijks athenaeum te Franeker*, 2 vols. (Leeuwarden 1878-89) vol. ii, p. 217-26; Svijsling, J. P., *Die statuten-theorie in Nederland gedurende de XVII de eeuw* (Bois-le-Duc 1893) p. 88-114.

HUBER, VICTOR AIMÉ (1800-69), German social reformer. Huber was a professor of modern languages and history at the universities of Rostock, Marburg and Berlin. In the struggles over the Prussian constitution between 1840 and 1848 he represented a strong Christian and conservative point of view; he attacked the constitutional ideal and urged the creation of an advisory parliament representing the organized social classes or orders. This reform presupposed raising the industrial workers to the status of a full fledged social order with its own corporative organization and improving their economic condition; these changes he considered necessary also for moral and religious reasons. While most of the conservatives were exclusively agrarian, Huber recognized the necessity of industrial development in Germany; he wished, however, to safeguard society from an uncontrolled capitalist development. Inspired by English experience he became the champion of the cooperative idea in Germany. At the time when Raiffeisen was organizing cooperatives among the peasants and Schulze-Delitzsch among the artisans Huber spread propaganda for building and consumers' cooperatives among the industrial workers. He proposed the building of cooperative settlements of workers' homes, which were to be financed by the state, the church and the propertied classes. The settlements were to meet the household needs of the workers through cooperative wholesale buying and eventually through cooperative

production of many commodities. An important function of the settlements was to preserve the home and family life. He demanded the promotion of his reforms by the upper classes, to whose social conscience he made a forceful appeal. When this appeal was rejected, he came to rely on the more democratic self-help of the workers and favored the organization of trade unions, which arose in Germany after 1860. He sharply attacked, however, the socialist labor movement, in which he saw nothing but atheism, communism and anarchy.

Huber played an important part in linking up the cooperative idea with the Christian-conservative political philosophy which regards the state as a spiritual organism. Although many of his proposals were formally adopted, he had no direct influence on the development of consumers' cooperation in Germany.

INGWER PAULSEN

Works: V. A. Hubers ausgewählte Schriften über Social-reform und Genossenschaftswesen (Berlin 1894); Die englischen Universitäten, 2 vols. (Cassel 1839-40), abridged translation by J. P. Simpson (London 1843).

HUBERT, HENRI (1872-1927), French sociologist and historian. Hubert was professor of the history of European primitive religion at the École des Hautes Études, assistant curator of the Musée des Antiquités Nationales and from 1902 until his death professor at the École du Louvre. He published numerous treatises and reports in the fields of archaeology and prehistory but was particularly interested in the history of religions and of civilizations. He was among the first to attach himself to Durkheim, whose fervent and yet independent disciple he became. In the articles "Essai sur la nature et la fonction du sacrifice" and "Esquisse d'une théorie générale de la magie" (in *Année sociologique*, vol. ii, 1897-98, p. 29-138, and vol. vii, 1902-03, p. 1-146) published in collaboration with Marcel Mauss, he sought to demonstrate the part played by society in religious and magical activity. He contended that the sacrifice was a complicated means of communicating with things and beings defined as sacred by society and that magic despite its technical appearance comprises a system of collective ideas common to magic and religion, which he called mana. It was through an extension of these researches that Hubert with Durkheim and Mauss encountered the problem of the collective origins of

reason, a question which he discussed in his important treatise, *Étude sommaire de la représentation du temps dans la religion et la magie* (Paris 1905). He also dealt with the collective origins of mythology in his article on the "Culte des héros," which served as an introduction to Czarnowski's *Le culte des héros et ses conditions sociales: Saint Patrick, héros national de l'Irlande* (Paris 1919).

HÜBNER, MARTIN (1723-95), Danish publicist and statesman. Hübner was one of the eighteenth century writers who participated in the conflict of ideas as to the legal status of neutral commercial vessels in naval warfare. In his chief work, *Traité de la saisie des bâtimens neutres* (2 vols., The Hague 1759), Hübner took a position representing the extreme backward swing of the pendulum from the contemporary political policy which conceived of naval warfare solely as an aggressive, imperialistic means for establishing a nation's naval supremacy. Against the prevailing practise of ruthless treatment of neutrals he consistently advocated the preservation of the sovereignty and equality of neutral states according to international law, with respect to the safeguarding of neutral merchantmen at sea in times of war. To give effect to this basic concept he invented the fiction that every neutral merchantman is a part of the national territory of the neutral state to which it belongs and so shares in its inviolate character. It followed that a belligerent had no more right to seize enemies' goods and contraband of war from neutral vessels at sea than to invade neutral territory; the rule should be "free ship, free goods." Furthermore the right of visit and search could be exercised only to ascertain the national character of a vessel. Nor did a belligerent have the right of prize court jurisdiction. In place of this Hübner proposed as a maximum of both the neutral's compliance and the belligerent's power an international prize court composed of judges appointed by both states, thus avoiding a situation in which the belligerent, a directly interested party, would be both prosecutor and judge in the same case. In advocating the strict construction of the principle of sovereignty, however, Hübner and others who followed his

doctrine, for example Galiani, came into sharp conflict with another principle, which had prevailed in international law since Grotius; namely, that of the freedom of the high seas.

ROLF KNUBBEN

Consult: Wheaton, Henry, *History of the Law of Nations in Europe and America* (New York 1845) p. 219-29; Cauchy, E., *Le droit maritime international*, 2 vols. (Paris 1862) vol. ii, p. 82-91; Butler, G., and Mac-coby, S., *Development of International Law* (London 1928) p. 262-63.

HÜBNER, NIKOLAY PETROVICH (1858-1919), Russian cooperator. Hübner studied at the Military Academy of St. Petersburg and was judicial officer attached to the military court of Moscow. He was one of the first to appreciate the full significance of the cooperative idea for the economic progress of the Russian people and he also welcomed cooperation as providing an opportunity to translate into practise the ideals of Christianity. Hübner started his career as co-operator by organizing a cooperative store for the army officers in Moscow; it grew into a large and well organized business and during the World War rendered enormous services to the army. In 1896, when the cooperative section of the All Russian Congress of Trade and Industry decided to establish the Moscow Union of Consumers' Societies, Hübner was chiefly responsible for securing the permission of the government, a considerable achievement at the time. He aided materially in the establishment of the union and remained its leader until 1905. During the World War the union was reorganized into the All Russian Central Union of Consumers' Societies, universally known as the Centrosoyus. Of equal importance was his role in the foundation of the Moscow People's Bank, the central cooperative bank, in 1912. Both in the preliminary work and later as the first president of the bank's council Hübner proved one of the most ardent workers in the cause. Hübner's literary legacy is slight; he contributed frequently to *Soyuz potrebiteley* (Union of consumers), a magazine founded by him in 1903; and he is the author of an admirable, informative book, *Sistema kooperatsii* (The system of cooperation, Moscow 1911).

A. N. ANTSEFEROV

HUDSON, GEORGE (1800-71), English railway promoter. Hudson, an apprentice and then partner in a drapery business in York, successfully established the York Banking Company in 1833 and four years later became lord mayor of

that city. He took up railway promotion at a time when the new means of transportation had overcome opposition and promised to pay good dividends. He became chairman of the York and North Midland Railway in 1837 and quickly rose to power in the railway world. In 1843-44 he formed the Midland Railway Company by an amalgamation of two end-on systems with a competing line. Within a few years as chairman of the Midland company and half a dozen others Hudson dominated 1016 miles of railways. He personified amalgamation and gave a powerful impulse to the movement; he also personified the railway boom of the mid-forties. Hudson was now known as the railway king; he became a member of Parliament and leader of the "railway" party there and participated in numerous speculative projects. The crash came in 1848-49. Hudson was found to have misappropriated large sums of money and was forced to resign his chairmanships. His career was ended, although he made partial restitution and continued to sit in the House of Commons until 1859.

Hudson was the outstanding figure in the consolidation of English railways; he was essentially the leader needed to follow up the work of the engineers who had built the early railways. Besides establishing the principle of combination he adapted the organization of his railways to provide for expansion and systematized the staff arrangements. The Midland Railway, his central achievement, was always a pioneer compelled by its position between the North Western and the Great Northern to fight for traffic. In improving and popularizing third class traffic (previously neglected), introducing sleeping and dining cars and speeding up its time table the Midland was always stimulating that competition in facilities which, rather than competition in rates, is a marked feature of English railway history.

EDWARD CLEVELAND-STEVENS

Consult: Stretton, C. E., *The History of the Midland Railway* (London 1901); Cleveland-Stevens, E., *English Railways* (London 1915) ch. vii; Tomlinson, W. W., *The North Eastern Railway* (Newcastle 1914) chs. ix-x, xv and xvii. See also articles in *Fraser's Magazine* vol. xxxix (1849) 607-18, and vol. xl (1849) 106-20.

HUÉ, OTTO (1868-1922), German labor leader. Hué was one of the outstanding organizers of the miners' union, in which he played a leading role for many years. At twenty-five he began his activity in the labor movement, contributing frequently to the journal of the union of miners and smelters. He became editor of the journal in 1894 and later president of the union.

Hué had espoused socialism and strongly favored cooperation with the Social Democratic party. In addition to the regular trade union work for higher wages and shorter hours he developed an active campaign for the introduction of safety devices and social insurance among the miners and smelters. He was particularly interested in workers' education, which he considered an important aspect of unionism. Hué was influential in Social Democratic politics; he was a member of the Reichstag from 1903 to 1911 and of the Prussian Landtag from 1903 to 1918, where he fought especially for the interests of the miners. During the World War he accepted the majority Social Democratic position—defense of the nation but no annexations. When the republic was established in 1918, Hué was appointed to a number of government positions, among them that of commissioner of mining for Westphalia. In 1920 he was again elected to the Reichstag and urged socialization of the mining industry. Hué was keenly interested in the history of mining and in the international problems of the industry, interests which appear brilliantly in his work *Die Bergarbeiter* (2 vols., Stuttgart 1910-13). After the war his international point of view expressed itself in endeavors to revive the International Federation of Miners. The first post-war congress in 1920 expressed its appreciation of Hué's work.

Consult: Limbertz, H., in *Das internationale Handwörterbuch des Gewerkschaftswesens*, pts. i-v (Berlin 1930-) pt. iv, p. 779-80; Osterroth, N., *Otto Hué, ein Lebensbild für seine Freunde* (Bochum 1922).

HUFELAND, GOTTLIEB (1760-1817), German economist and jurist. Hufeland was one of the outstanding representatives of Smithian economics in Germany. In accord with his training in law and Kantian philosophy he sought to provide liberalism with a philosophical basis in natural law, particularly in the principle that security is the primary function of the state. While his penetrating analysis of some of Smith's concepts had a far reaching influence upon subsequent economic thought in Germany, Hufeland can hardly be credited with many original contributions. Indeed it was not difficult for Roscher to point out the theoretical confusion which marked Hufeland's main work (*Neue Grundlegung der Staatswirtschaftskunst* . . . , 2 vols., Giessen 1807-13; 2nd ed. of vol. ii as *Die Lehre vom Gelde und Geldumlaufe*, Giessen

1819). The book contains, however, an early version of the subjective theory of value and elements of a productivity theory of distribution based not merely on the physical productivity of the individual factors but on their value productivity as expressed in the process of price formation. It is likely that these views influenced Hermann as well as Thünen. Hufeland's most lasting contribution was his theory of profit. He viewed profit as an independent income category coordinate with wages, interest and rent and constituting in part a payment for risk and in part "rent of ability." He also stimulated monetary theory by emphasizing the role of velocity of circulation of money during inflation. Following J. B. Say he opposed the legalistic theory which was widely held at the time, according to which the circulatory power of money depends upon government fiat.

M. PALYI

Consult: Roscher, Wilhelm, *Geschichte der Nationalökonomik in Deutschland* (Munich 1874) p. 654-62; Gross, Gustav, *Die Lehre vom Unternehmervergewinn* (Leipzig 1884) p. 75-77.

HUGHES, THOMAS (1822-96), English lawyer, writer and pioneer in cooperative and educational movements. He was educated at Rugby under Thomas Arnold and at Oriel College, Oxford; in 1848 he was called to the bar and in the same year was introduced by F. D. Maurice, then chaplain of Lincoln's Inn, to the small group of Christian Socialists who were at that time beginning their work. Hughes threw himself with ardor into the experiments in cooperative production in which his friends J. M. Ludlow and Charles Kingsley were the pioneers; with E. V. Neale he linked this movement with that for cooperative distribution initiated at Rochdale and already spreading in the north of England. In 1852 he helped to secure an act of Parliament giving legal protection to cooperative societies. He participated enthusiastically in the formation of the Working Men's College in 1854 and was principal from Maurice's death in 1872 to 1883. From 1865 to 1874 he was in Parliament and although he did not distinguish himself he remained actively interested in legislation for the laboring classes.

Hughes was bitterly opposed to slavery and on that issue he championed the North in the American Civil War. He visited the United States in 1870 and returned in 1880 as president of the Board of Aid to Land Ownership, a colonization venture to facilitate the migration of

upper middle class Englishmen. The site chosen was a tract of land—later named Rugby—in the hills of Tennessee, and it was hoped to make it a complete realization of "Christian communism." Hughes had great faith in its success and spent on it almost his entire fortune, but the scheme proved a complete failure.

Hughes is best known as the author of *Tom Brown's School Days* (1857) and of its rather less sensational sequel, *Tom Brown at Oxford* (3 vols., 1861). The former is a glorification of Arnold as schoolmaster and of the rugged virtues for which its author found so satisfactory a creed in Kingsley's "muscular Christianity." The book's influence on thousands of schoolboy readers was probably of equal significance with Hughes' more direct activities for social reform.

CHARLES E. RAVEN

Consult: "Fragments of Autobiography," ed. by H. C. Shelley, in *Cornhill Magazine*, n.s., vol. lviii (1925) 280-89, 472-78, 563-72; Ludlow, J. M., "Thomas Hughes and Septimus Hansard" in *Economic Review*, vol. vi (1896) 297-316; Park, Joseph H., "Thomas Hughes and Slavery" in *Journal of Negro History*, vol. xii (1927) 590-605; Hamer, M. B., "Thomas Hughes and His American Rugby" in *North Carolina Historical Review*, vol. v (1928) 390-412.

HUGO, GUSTAV (1764-1844), German jurist. The son of a conservative high official in Baden, Hugo attended a *Gymnasium* in the neighboring French town of Mömpelgart. He studied at the University of Göttingen, where he associated closely with the Romanist Pütter, the philosopher Feder and the historian Ludwig Timotheus Spittler, the latter influencing him particularly. He subsequently became professor at Göttingen, where he spent the greater part of his life.

Hugo's significance lies in two directions, marking the turning point and the beginning of a new era in the history of jurisprudence. He led the way to the development of the historical jurisprudence which is now accepted as a matter of course and into the glaring confusion of the *usus modernus pandectarum* he brought clarity and order as to fundamental principles. He separated the Roman, that is the Justinian, elements from the customary law elements which had been added by German theory and practise. He also took up the struggle against the fantasies of natural law, whether derived from the nature of things or the nature of reason.

Behind both of his tenets, which he developed with sharp and unreserved criticism even against his teachers, there is the intellectual merit of his application of the methods of natural science to

the methods of jurisprudence, which was the result of his own trend toward empiricism, strengthened by the study of Kantian philosophy. It was that which on the one side led him in a historical direction. From the beginning of his activities as a teacher he saw his problem as one of departing from the usual treatment of Roman law as a finished legal product in order to disclose the historical development behind single texts, in the sphere not only of private but of public law, especially constitutional law. He zealously went to the pre-Justinian sources. Hugo was really the founder of what is now known as the historical discipline of Roman law. This, however, does not make him the founder of the historical school. Although he gladly welcomed and sponsored it and its chief representative, Savigny, Hugo did not, according to his own declaration, consider himself one of its adherents. He never accepted its romantic imponderables; for instance, the theory of the importance of the folk spirit.

In his resistance to the current of natural law Hugo was again guided by his strong empiricism and rationalism. It was neither juridical nor logical to want every maxim of positive law to follow a supreme thesis assumed a priori. Principles and consequences were never absolute. The variety of systems of natural law showed that it was possible to prove every legal institution right or wrong with the help of natural law speculations. The conception of justice changed with the historical changes in social conditions. An economic order without the institution of private property was conceivable. He thus developed fundamental pacifist and socialist ideas unreservedly on the basis of pure rationalism. The apex of his ideas was the concept of a world state. His thought expressed the change in thinking from absolutist narrowness to relativist variety and in breadth and independence was far in advance of his time.

HUGO, VICTOR-MARIE (1802-85), French writer. Hugo was a fervent apostle of the ideals of modern democracy. Although he was at first a royalist, his sympathies gradually grew more liberal and during the reign of Louis-Philippe his political ideal became pragmatically "a republic in fact, and a monarchy in word." He was still a conservative republican when he was elected to the Constituent Assembly after the overthrow of Louis-Philippe in 1848, but in the following year after his election to the legislative assembly under Louis-Napoleon he became suddenly an extreme radical. After the coup d'état of 1851 he was forced into exile, which he spent successively in Brussels, Jersey and Guernsey. In 1870 after hearing of the fall of the empire he returned to Paris and in 1871 was elected to the popular assembly (Bordeaux) convened to consider whether France should continue the war with Germany. Annoyed with the opposition he resigned and went out of France, first to Brussels, and then, because of his too frank partisanship for the defeated Commune, to Luxemburg and, in 1872, back to Guernsey. In 1876 he was elected to the Senate but his significance in practical politics was ended.

Hugo's *Napoléon le petit* (1852), *Les châtiments* (1853) and *Histoire d'un crime* (1877-78) were the products of his exile and his furious hatred of the empire. Less passionate although perhaps equally polemic was his earlier work, *Le Rhin* (1842), in which he embodied his conviction of the essentially Gallic nature of the left bank of the Rhine and his belief in a desirable and feasible United States of Europe. Hugo's ideal of democracy and his belief in continuous "progress" became more and more mystic and brought him finally to his testamental *Fin de Satan* (1886), in which, all social and religious questions being explained in terms of a universal system, the Principle of Evil is pardoned and the world set free.

Liberty was a catchword for Hugo, but it implied for him no distinct counterpart of responsibilities. It meant, first, opposition to censorship and revolt against the "rules" of post-classicism; then, dislike of whatever appeared as oppression by church or state; last, to a large extent hatred of any encroachment on personality. Young France hailed more and more, in

1830, 1848 and 1875, this social gospel embodied in magnificent books of verse and prose without noticing that Hugo's creed, Napoleonic in its secret aspirations, often lacked social conscience and due respect for the real needs of the times.

There is much of Rousseau in Hugo's social philosophy—his belief in instinct and the goodness of man, his adoration of children, his scorn of hierarchies and dogmas. Perhaps the most complete expression of his social ideals is *Les misérables* (1862). The people are the true depositories of divine wisdom, with instinctive views resting on a principle of goodness and justice which has been stored away in the hearts of mankind while society has forgotten its meaning. Thus "education" (which is deciphering a hidden knowledge in instinctive minds), universal suffrage (which makes distinct the *vox populi*), suppression of the death penalty and rehabilitation of the convict and the fallen woman are of equal importance with his concrete schemes concerning the development of modern cities and the welfare of masses. How is Gavroche, the small city boy, not corrupt but ignorant, to be made a responsible member of the community without the help of the family and of the catechism? This is in a way the main issue of the novel and it may be said to be the chief problem in Hugo's sociology.

HUMAN NATURE. The significance of the idea of human nature for the social sciences gathers about three questions: (1) Are contempo-

rary political and economic institutions necessary products of human nature? Or, more generally, does the very constitution of human nature show that certain social arrangements are likely to be successful while others are doomed to failure? Is war, for example, inevitable because of facts of human nature? Is self-interest so ingrained in human nature that the attempt to base industry on anything except a competitive struggle for private gain is sure to fail? (2) How far is human nature modifiable by deliberate effort? Or, in other words, which is more important, nature or nurture? Or, in still another form, how are heredity and environment related to one another? Which is more potent in the determination of behavior? (3) How great and how fixed is the range of variations in human nature between individuals and between groups? Are some racial or social groups by nature definitely inferior to others because of causes which cannot be altered? The same question is asked concerning individuals within each group.

These questions are bound up with controversies involving intense feeling. They largely condition the differences between conservatives and liberals, between aristocrats and democrats, between nationalists and internationalists. They are associated with emotions of complacency, pride and egoism. It is therefore extremely difficult to attain impartiality with respect to them, and discussions are often apologetics for some position already assumed on partisan grounds. There is, however, one incontrovertible fact about human nature—that the term has been used in a variety of senses and that in the history of thought there has been some correspondence between the interpretation of the concept and the general institutional and intellectual character of the time.

Four principal conceptions of the term may be mentioned: (1) The term is used to designate an alleged original and native constitution; that which is instinctive instead of acquired. There is a possible ambiguity here unless it is made clear whether the native constitution is taken to be common to all normal human beings or is one peculiar to particular individuals. (2) Human nature is defined in terms of alleged psychological powers or faculties, the "psychological" being placed in antithesis to both the physical and the social. Every normal human being is said to have certain powers, like perception, judgment, memory, desire. These powers are formal; they are to be distinguished from what is perceived, remembered, thought about, wanted. The ma-

terial content is held to come from sources outside of human nature, from either physical nature or social life. This assumed dualism between human nature and other nature has been so widely prevalent that it often affects discussions without being avowed: to many persons it is a direct product of "common sense." It has behind it a long intellectual history: formulated by John Locke, it was taken up by the British liberal school and became the basis of a distinction, on one side, between intrinsic "natural" law and "natural" rights (which are fixed and universal in the formal structure of human nature) and, on the other side, between artificial civil and political rights, which vary with conditions. (3) Human nature is in itself empty and formless and is therefore capable of being molded by external influences. Locke himself had declared that the mind is a piece of blank paper as far as any particular ideas and beliefs are concerned, although he had endowed it with certain formal faculties or powers. His French successors, like Condillac and particularly Helvétius, thought they were rendering him logically consistent when they held that "faculties" also were impressed on the mind by experience, mind being nothing but susceptibility to impressions from without. In this view education and the influence of the environment are all powerful. If men are corrupt and prejudiced, seeking only their private power and profit, it is only because institutions have formed them in their own likeness. (4) Human nature cannot be properly conceived or defined in terms of the constitution of individuals either native or acquired. Human nature can be known only through its great institutional products—language, religion, law and the state, the arts. As displayed in individuals it is merely potential; it develops into reality under the influence of cultural institutions, which form the content of objective mind and will. This theory drew some of its support from the teachings of Aristotle, especially in applying the distinction of "potential" and "actual" to human nature. But it was formulated especially by the school of institutional idealists headed by Hegel. Aside from any metaphysical formulation it influenced for a generation or more German students of comparative language, religion and law and was a great factor in producing the conception of a social mind which was made the basis of an entire school of social psychology.

It is obviously hopeless to look for agreement as to the modifiability of human nature or its relation to society, where the very content of the

term is so variously conceived. The last named conception, for example, expressly denies that the facts of original, or native, structure and instinct which the first conception treats as constituting human nature are anything more than crude and undeveloped potentialities, so inchoate in themselves that we could not even give them names were it not for knowledge of what they are capable of becoming, a knowledge which is had only by noting the institutional forms of a mature culture. We have here an instance of the controversy as old as Aristotle as to whether "nature" is to be defined in terms of origin or of complete development, i.e. of "ends." At first sight it might seem as if the difference could be explained away as merely one in verbal definition, one school using the word for one set of facts and the other school for another. If this were all there might be disagreement about the application of a word and yet agreement about the things to which different names are applied. Such, however, is not the case. The supposition that there is such a thing as a purely native original constitution of man which can be distinguished from everything acquired and learned cannot be justified by appeal to the facts. It is a view which holds good only when a static cross section is taken; when, that is to say, growth is ignored. The theory takes, as it were, a snapshot of man at, for example, birth, ignoring past history in the uterus and future history when the supposedly fixed and ready made structures will change as they interact with surroundings. Biologically all growth is modification and all organs have to be treated and understood as developments out of something else and as pointing forward to still something else. The conception of a fixed and enumerable equipment of tendencies which constitutes human nature thus represents at the best but a convenient intellectual device, a bench mark useful for studying some particular period of development. Taking a long enough time span, it is fruitless to try to distinguish between the native and the acquired, the original and the derived. The acquired may moreover become so deeply ingrained as to be for all intents and purposes native, a fact recognized in the common saying that "habit is second nature." And, on the other hand, taking a long biological evolution into account, that which is now given and original is the outcome of long processes of past growth.

Practically, however, with reference to the possibility of control the distinction between the native and the acquired is important. Barring

some future possible development of eugenics, our practical control of growth begins at birth; in controlling future developments we must start with what exists at that time. Existing organs, impulses, instinctive tendencies, form the resources and the capital on which future development must build. Included in this native stock is, however, the tendency to learn and to acquire. That the tendency to learn and hence to modify and be modified is itself part of the native (and hereditary) structure may appear too much of a truism to need statement. Nevertheless, this must be borne in mind, since it is decisive in showing how impossible it is to make any hard and fast distinction between the natural and the acquired, the native and cultural. The capacity for modification is part of the natural make up of every human tendency; it belongs to an unlearned equipment (as that is defined at a particular time) for learning, in which process it is itself changed. Recognition of this fact will save us from devoting energy to unreal questions and lead to concentration upon the important ones: What are the limits to modification through learning? How does the modification concretely proceed? How is it controllable?

On this question—in fact, on all issues concerned with human nature—men have entertained historically a variety of views. Classic Greek thought is based upon belief in the natural and inherent inequality of men. The most widely known expression of this point of view is Aristotle's statement that some men are slaves "by nature" and hence are to be ranked with tools and domestic cattle as means of production. The entire class of mechanics even if legally freemen belongs in this category, being by nature shut out from the truly free or liberal life, that of the mind. Retail shopkeepers are means also of serving material purposes and do not belong to the realm of ends. While this view was to some extent a rationalization of social prejudices which had been incorporated into the Athenian system it was also something more—a systematically thought out interpretation of human nature. In this interpretation the reason given for holding that some men are slaves by nature—even more important than the view itself—was that they possess an inherent deficiency in rational insight. Reason is the governing power in man; it is a condition of self-government and participation in civic government. Impulses and passions must be kept in subjection to rational aims unless there is to be social and moral chaos. Hence it is intrinsically proper that some persons should be

the animate instruments of others. The mass of non-Athenians who were not citizens and also not slaves but classed as mechanics (i.e. tools) by nature were said to occupy a lower status morally than slaves, since the latter, living in a certain intimacy of communication with their masters in the household, attained a kind of reflected rationality. Women were also ranked as constitutionally inferior and hence as properly subject to fathers and husbands; so also were the barbarians as compared with the Greeks, although the northern races, in whom spirited impulses are strong, were ranked higher than Asiatics, in whom appetites for ease, possession and passive enjoyment were dominant.

After the decay of Athenian culture at the time when the stoics were the ruling school of thought it was assumed as axiomatic that men are equal by nature and that differences among them are differences of status due to convention, to political organization and to economic relations, which are instituted rather than natural. So complete a revolution in thought in a few centuries is difficult to account for, but among the influences may be discerned the fact that the cynic precursors of the stoics were drawn largely from a proletariat class having no citizenship. The decay of the city-state with its intimate organization of loyalties, the growth of the impersonal Roman Empire, the weakening of local ties and the development of cosmopolitan sentiment were among the objective forces at work.

The doctrine in its original form did not have radical implications regarding existing institutions. The conception that political and economic inequality was based not on nature but on institution carried with it no attack on the latter. The stoic idea was favorable to the spread of a moral sentiment of confraternity among individuals as individuals, but in general it called for loyal acceptance of one's status in the existing social order. When the Christian church proclaimed the same doctrine of natural equality, it was also interpreted in a religious and moral sense free from political implications. Doctrines, however, outlive their original context, and at later times the stoic and Christian idea of natural equality was given a revolutionary interpretation.

The blend of Greek thought and oriental culture known as Hellenistic and centering at Alexandria took another turn, adverse to attaching value to nature in any form, physical or human. Because of what Gilbert Murray has termed "failure of nerve" the age centered its intellectual and emotional interest on the super-

natural and on the special means by which favorable relations with it were to be established. Little value was attached to social institutions of any kind in comparison with the method by which redemption of the soul was to be effected. The depreciatory view of nature which was instilled became associated with religion in the degree in which the latter lost the definite civic form it had in classic antiquity.

The main direction of thought in the mediaeval period represents a synthesis of ideas derived from different sources. There was the idea of the natural equality of men, an idea especially cherished during the earlier period in which the membership of the Christian churches was composed mainly of the disinherited. Morally speaking, a strongly democratic sentiment was inculcated. There was also, however, the tradition of the insignificant value of the natural in comparison with the spiritual interests represented by a superworldly kingdom. In fact, because of the corruption of nature due to the fall of man complete subjection of the natural man to the discipline and sacraments of the church was required, since the church was the divinely instituted and supported guardian of spiritual truth. The ascetic influences which prevailed in monastic circles accentuated the depreciatory view taken of the natural. At the same time, as the church became established as the supreme European institution and its doctrine took shape in scholastic philosophy, its official theory grew far from hostile to the conception of nature. On the contrary, under the influence of revived Aristotelianism it gave nature a place and validity of its own within definite limits; namely, as subordinate to revelation wherever the latter had spoken authoritatively. Moreover, as the struggle for authority between church and empire became acute, the doctrine of the conventional and instituted or positive character of political authority took a form distinctly hostile to the claims of the latter, so that the teachings of the church theorists helped to furnish later revolutionaries with weapons of attack upon the authority of autocratic governments.

It is a commonplace that what is called the modern period was marked by a new interest in and by a new respect for nature. This extended to human nature. There were explicit attempts to free moral and political theory from ecclesiastic and indeed from all institutional influence. The positive side of this movement found the authority needed for the new morals and politics in human nature. But a cleavage showed itself

almost at once with respect to the constitution of human nature in a controversy as to what element is dominant "naturally" and must therefore according to the theory be considered the support of political theory and practise. One school foreshadowed by Grotius and developed by his continental successors in the natural law tradition emphasized "reason" as the important factor. This, however, had little but the name in common with the classic Greek conception, although somewhat more kinship with the stoic conception. Reason was the universal element; the universal was the common, and the common was the bond of union among all men. It was the social tie which holds all human beings together in society even apart from and prior to the formation of a political state. Its social nature is expressed in the natural, or moral, laws which underlie political organization, and to which the latter must conform if it is to be just. A series of jurists and philosophers deduced the state with its basic laws and its systems of civil rights from this element in human nature.

English thought took a different turn in the seventeenth century, in which it was followed upon the whole by influential French thought in the eighteenth century. Continental thought was meant to justify law and authority by showing their accord with rationality as the reigning element in human nature. English thought was concerned to protect individuals from the encroachments of governmental action and, when necessary, to justify revolt. Psychologically it started from desire and emotion instead of reason and ended in a theory of rights instead of obligations. The writings of Thomas Hobbes, the real founder of British theory, are important in this connection even though outwardly he employed his doctrine to substantiate the claims of a powerful centralized state. In so doing he was actuated by hostility to the claims of churchmen—Presbyterians, Independents, Church of England adherents as well as Catholics—and he appealed directly to the affective side of human nature as primary. Moved by the civil wars and disintegration of his time, he appealed especially to fear and the need of security. English political thought after Hobbes consistently interpreted human nature in terms of the primacy of non-rational factors, pointing out that these employed reason as a means of obtaining satisfaction for themselves.

With the rise of the new industry and commerce, however, an important variation was introduced. The economists who set out to give

intellectual expression to the rising industrialism started from the affective side of human nature in accordance with prevailing English doctrine. They developed, however, a much more systematic theory than had ever been developed of the nature and operation of wants, out of which came a new conception of natural law. Economic activity, on this view, is basic; from it are derived the natural, in the sense of non-artificial, laws of human conduct. Society is the product of the efforts of human beings to satisfy their wants, since division of labor, exchange and permanent property are involved in this satisfaction. Government and political action exist in a secondary way in order to give security to the free play of economic forces. In its early stage the theory was thoroughly optimistic in its anticipations of the future of society when freed from the artificial regulations of political action. The conception of natural harmony was implicit or explicit. The land and rent theory of Ricardo and the population theory of Malthus introduced factors of inevitable disharmony and conflict which later gave a pessimistic turn to the view entertained of the workings of human nature.

It would thus appear that during the greater part of the history of European thought conceptions of human nature have been framed not with scientific objectiveness but on the basis of what was needed to give intellectual formulation and support to practical social movements. There is a reason for this beyond the ordinary tendency to use ideas to further practical activities. A new social movement brings into play factors in human nature which were hitherto dormant or concealed; in thus evoking them into action it also presents them to the notice of organized thought. A striking example of this fact is the reversal by most recent theory of the place attributed to wants in classic Greek speculation. In Greek thought wants were a sign of defect; they were to be kept under strict control inasmuch as they were the chief causes of social and moral disorder. Since the industrial revolution theory has generally held that wants are the motors of social progress, the dynamic force in creation of initiative, invention, the production of wealth and new forms of satisfaction.

The factors which have of late operated to put the question of the constitution of human nature on a more objective basis are the rise of a psychology with biological foundations and the development of anthropology. The psychological factor has made it clear that if definitive results are to be reached regarding the native or original

equipment of man they must be sought from physiological study correlated with structural studies of human behavior at various stages of growth, especially intra-uterine and immediately postnatal. The native equipment is, roughly speaking, identical with the biological equipment; recognition of this fact will in time take the theories of the matter out of the area of speculation into that of observable fact. Anthropology, on the other hand, has made it clear that the varieties of cultural and institutional forms which have existed are not to be traced to anything which can be called original unmodified human nature but are the products of interaction with the social environment; they are functions, in the mathematical sense, of institutional organization and cultural traditions as these operate to shape raw biological material into definitively human shape. If we except the extreme partisan stand, it may be regarded as now generally accepted that the immense diversities of culture which have existed and which still exist cannot possibly be derived directly from any stock of original powers and impulses; that the problem is one of explaining in its own terms the diversification of the culture milieus which act upon original human nature. As this fact gains recognition, the problem of modifiability is being placed upon the same level as the persistence of custom or tradition; it is wholly a matter of empirical determination, not of a priori theorizing. It cannot be doubted that there are some limits to modifiability of human nature and to institutional change, but these limits have to be arrived at by experimental observation. At present there are no adequate experimental data on which pronouncements may be based. Moreover when such limits are found it will be important to discover whether they are intrinsic and absolute or whether they are to some extent due to limitations of our technique for effecting change. Certainly some of the limits existing at any particular time will recede, exactly as have the earlier limits in control of the energies of physical nature, with increased knowledge of causal factors. At the present time, for example, we can predict to some extent on a statistical basis the effects of educational measures. But the effect of education upon the development of a particular individual is, as far as foresight is concerned, still largely a matter of guesswork. It would be hard to find a fact by which to illustrate more forcibly the limitations of our present technique in effecting modification of human nature. Although schools abound, education as a controlled process of

modification of disposition is hardly even in its infancy.

The present controversies between those who assert the essential fixity of human nature and those who believe in a great measure of modifiability center chiefly around the future of war and the future of a competitive economic system motivated by private profit. It is justifiable to say without dogmatism that both anthropology and history give support to those who wish to change these institutions. It is demonstrable that many of the obstacles to change which have been attributed to human nature are in fact due to the inertia of institutions and to the voluntary desire of powerful classes to maintain the existing status. With regard to the possibility of economic reconstruction history demonstrates the comparative youth of the present regime; and revolutionary societies may be regarded as social laboratories in which is being tested the possibility of securing economic advance by means of other incentives than those which operate in capitalistic countries. For the immediate present all that can reasonably be hoped for with reference to the general issue of human nature are: a willingness to substitute special concrete plans of modification for wholesale claims and denials; the growth of a scientific attitude which will weaken the force of ideas and battle cries coming from the past; willingness to see social experiments tried without interference by outside force; and the use of educational means that are regulated by intelligent foresight and planning instead of by routine and tradition.

HUMANISM

HISTORICAL ASPECTS. A movement which represented an extensive change—almost in the nature of a mutation—in art, literature and thought took place in western Europe at the close of the Middle Ages and in early modern times. More than any other series of events it embodied the transition from mediaeval to modern times. On its literary and intellectual side this movement has been called humanism. Underlying it were the phases of a commercial revolution—an increase of trade, of wealth, of banking, of accumulation by rich individuals and taxation by governments. That humanism should first arise in Italy was but a reflex of the fact that it was there that a wealthy commercial life in cities and at luxurious courts first appeared. Only in a consumers' civilization such as the Italian, founded on wealth and leisure, could such a movement take place. The early humanists were the secretaries, librarians, teachers, sometimes the courtiers and officials, sometimes themselves the princes and prelates and great merchants of the cities and courts. Some sixty or eighty Italian writers obtained enough fame in the later decades of the fourteenth century and during the fifteenth to exert a wide influence on their own time, and they have remained objects of literary and intellectual interest ever since. Many thousand pages of Latin and Italian prose and verse remain to testify to the scholarship, the taste and the industry of these and the lesser writers of their time. To the great majority of readers and students of later time it is the writing and the interests of these men that constitute humanism.

Humanism gathered largely about an increased interest in the Greek and Latin classics. The almost boundless variety of content, the perfection of form and the freedom of thought of the ancient writers provided admirable material for the uses of an awakened and critical but not a profound or an inventive mental activ-

ity. Moreover the Italians lived on the same soil as the writers of Roman antiquity and felt themselves their direct descendants. The language of the Romans of the classical age was the common language of mediaeval learning, law and the church. Quotation from the ancient writers was a familiar mediaeval practise, and what the ancients had known was the largest element in what the Middle Ages knew. But all this antique lore was subordinate in the Middle Ages to the doctrine, the discipline and the philosophy of the Christian church, to the scholasticism that dominated the universities, to the superstition that permeated knowledge and to the predilection of the time for religious interests. Now in a world of wider interests men studied the classics in a different spirit, with a new appreciation for their literary beauties, their variety of subject and their less inhibited outlook on life. They regarded the ancient writers as kindred spirits. Largely outside of the church and at first apart from the universities an ever increasing number of students, teachers, writers and officials immersed themselves in the study of the classics.

They were mighty hunters of manuscripts; within little more than half a century there were added to the list of classical writers known to the Middle Ages practically all those which were ever to be added. New works of Cicero, Quintilian, Nepos, Plautus, Martial, Ovid, Pliny, Varro, Tacitus and more obscure writers were discovered in old monasteries and elsewhere. The acquisition of the Greek classics soon followed. Greek teachers brought the tools of their trade with them. Guarino brought some fifty manuscripts from the East in 1408. Aurispa, a learned book dealer from Sicily, secured and brought to Venice more than two hundred in 1423, and Filelfo, secretary of the Venetian legation at Constantinople, brought home with him from that city copies of the works of at least forty Greek authors. All these were copied and recopied, edited, criticized, translated into Latin and Italian and eventually printed, and became the canon of all modern scholarship.

Study of the classics led to admiration, and admiration to imitation. Italian as a literary language, used by Dante and Petrarch in their poetry and by Boccaccio in his stories, yielded for the time to Latin; and skill and eloquence in the use of the ancient tongue rivaled discovery and scholarship in the reputation they brought. It was skill in the use of Latin for correspondence and state documents that led to the appointment of Salutati and Bruni as chancellors of Florence,

and of Aeneas Silvius, Poggio and Sadoletto as papal secretaries. Eloquence in Latin speeches of congratulation and other orations reduced hearers to tears, and mistakes of grammar or rhetoric awakened their ridicule. The pursuit of classic eloquence was for a time the most conspicuous element in humanism. Great reputations, such as those of a Bembo, Filelfo or Landino, were built up upon it.

More important than either scholarship or style was the variety of the subject matter of the writings of the humanists. This was due partly to the example of the ancients, partly to the increased alertness of mind and keenness of interest of their own age. The Middle Ages had of course their "bestiaries" and their historical and even scientific writings, but they were seldom the work of the intellectual leaders of their time. The greatest of the humanists, on the other hand, along with their editions of the classics, literary essays and letters, poems and orations, wrote geographies, like the description of ancient Italy by Biondo; histories, like those of Florence and the Italian towns by Machiavelli and Guicciardini; biographies, like those of the popes by Platina and of other famous men by Giovio, Cortesi and Vespasiano. They wrote about every conceivable human interest.

But it was, again, neither the form of the works of the humanists nor their subject that was most characteristic: it was their spirit. As compared with the piety or, at least, the ecclesiasticism of the Middle Ages, humanism was uninterested in theology. It was sometimes unregardful, at other times harshly critical of the church. In its thought it depended on no authority. Indeed so great was the departure of humanism from the Christian discipline of the Middle Ages that it was, on one of its sides, quite indistinguishable from paganism. This was also partly due to the influence of the ancient writers. It was impossible to read assiduously and receptively the writings of men who were either agnostics or whose gods were far away and unreal and retain any conviction of the existence of a personal, interested Christian deity. But the freedom of spirit of humanism was also a revolt from sacerdotalism, a layman's rebellion against the tyranny of the churchman, a declaration of independence of thought from the restrictions of ecclesiastical authority. It is true that some of the humanists were themselves ecclesiastics. They were papal secretaries, like Valla; bishops, like Bessarion and Sadoletto; cardinals, like Bembo and Accolti; even popes, like Nicholas v, Pius II and

Leo x. But these prelates were far from representative of the mediaeval church. Tolerant, secular in their interests, indifferent to religion, they were officials of the church as an institution but did not exemplify its spiritual life or insist on its spiritual authority. Wherever religion was genuinely earnest it entered into conflict with humanism, inseparably bound up as the latter was with emancipation of spirit and freedom of thought. In a later century and in more serious minded countries the religious enthusiasms of the Reformation proved to be as antagonistic to the survival of the free spirit of humanism as had been the strict religious uniformity of the Middle Ages.

It may have been this pagan, non-religious element in humanism, or it may have been the general character of the times, that was responsible for the large element of lubricity in its writing. But it is apparently the mere human love of a good story that accounts for the large part that anecdotes, facetiae, witty sayings and *adagii* play in its literature.

Education was an important element in the field of humanism; men wishing to know the classics sought instruction from those who already knew them. Greeks therefore established schools in which they provided an introduction to their language; native humanists gave instruction in the language, the style and the contents of the works of the ancients. The old town schools of the city republics called humanists to their service. Enlightened princes established schools for their own children and those of other distinguished persons, and in these also men who had attained fame because of their classical knowledge were appointed teachers. Even the universities gradually began to appoint, alongside their lecturers in law, medicine and theology, men of classical learning to give lectures on "rhetoric," which was stretched to include the new literary interests. These schools and classrooms were crowded with students. The teaching consisted of lectures, exercises and discussions on the classics; the content as well as the form of the ancient writers was studied. The grammar, etymology, vocabulary and even the style of the Latin and Greek languages and literature would never have created the enthusiasm that marked the humanistic schools. The teachers lectured on geography, politics, history and even medicine and science as they met those subjects in the ancient writers. It was this varied material that gave to the classics their preferred position in all later education, even after content had become subordinate to form and even after

other subjects of educational value unknown to the humanists had been discovered.

The theory as well as the practise of humanism exerted an influence on education at that time and has continued to do so. A many sided training, a program of education that would develop all that was characteristically human in an individual, that would fit him for the broadest and most effective use and enjoyment of life, attracted many of the fifteenth century Italian writers. Their plans were largely drawn from antiquity, especially from the ideas of Quintilian, but they were also affected by a revulsion from the training given by the church and by a recognition of the needs of their own time. Castiglione, in describing an education for the ideal man who will be able to take any position at any court, fills his pages with references to the ancient heroes and makes no mention of the mediaeval saints. It is obvious, however, that such a training was more suitable for a prince, a diplomat or a courtier than for a merchant or a man of lower degree. There was a certain aristocratic tendency in all humanist education. Anyone who entered upon the various courses of training was necessarily a man of station or was expected to become so. When education in the humanities had to be adapted to the needs of a more varied class of students it was inevitable that less attention should be paid to the matter and more to the form of the classics.

The humanists could not be expected to welcome the art of printing, which appeared in the very heyday of their fame. Most of them were or had been copyists devoted to beautiful handwritten codices, or collectors of manuscripts. These trophies became less notable when numerous copies of printed books could be procured much more cheaply. A presaging mind might also have dreaded a democratizing effect of such a wide spread of the *literae humaniores*. Nevertheless, printing soon spread from its obscure first appearance at Subiaco near Rome in 1465 to Rome itself, to Florence, to Venice, Bologna, Milan and soon to more than fifty small towns where obscure presses were set up. Within seven years the Subiaco press had printed 12,475 volumes. Before 1500, Symonds calculates, 4987 separate works had been printed in Italy. Compositors became more numerous than copyists and a more popular scholarship was needed in order that good editions of the classics might be printed. The most famous of all these printers, Aldus, was himself a typical humanist, a trained scholar, a student of Greek, a tutor of

young aristocrats and a friend and protégé of Pico della Mirandola. With borrowed capital he established his press at Venice in 1494, and by 1516 had published editions of thirty-three Greek authors. He cast his own Greek type, made his own ink, hired Greeks as compositors and workmen. Best of all, he sold his books at the lowest price he could possibly afford. He took especial pleasure in issuing his editions of Aristotle, Plato and Thucydides, of whom he had made a special study. He issued also many Latin and Italian works and set a standard of excellence in printing that was of immeasurable value. Thus one of the great achievements of humanism, the discovery and dissemination of the classics in manuscript form, was by the end of the fifteenth century carried to another stage, in which the literature was popularized and made accessible to all.

This advance came none too soon, for the movement, in so far as it was an Italian literary fashion, had become decadent. The immediate successors of those who had set the standards of scholarship were often mere pedants; the name humanist temporarily became one of ridicule rather than honor and the position of the mere scholar became far from happy. Some of the clergy denounced the irreligion of the humanists as heresy. While the corruption of the church was fast reaching its zenith a new piety was preparing the counter-reformation. The French invasions beginning in 1494 and the sack of Rome in 1527 came as signal evidences of the disintegration of the Italian society which had been so favorable to humanism.

In the meantime humanism had crossed the Alps. In France, Germany, the Netherlands, Spain, England and Scotland there appeared, with characteristic national differences, essentially the same set of interests as those which had given Italy her great repute. At the councils of Constance, Basel and Florence clergymen from north of the Alps met papal secretaries like Poggio and Bruni, lawyers like Vergerio and Bartolomeo da Montepulciano, all of them humanists of the first generation, and were deeply impressed with their classical learning and eloquence. Englishmen, Frenchmen and Germans were to be found as students at the schools of Guarino and Chrysoloras and as envoys or visitors at the courts of Rome and of the princes. They took back to their own countries the love of the classics, the critical spirit and the awakened intelligence of Italy. Before the end of the sixteenth century humanism became a

recognized interest and an efficient impulse toward knowledge, in greater or less degree, in every country of Europe.

It has formed one of the main threads in the web of all modern life. It has survived in various forms—classical scholarship, education in the humanities, temperamental resistance to ecclesiastical and political authority, a certain warm conviction that man himself is the center of the universe, and a basis for certain modern schools of philosophy and religion. A long line of men of great mental powers have devoted gigantic labors to classical scholarship. Beyond the Alps the primary place in the study of antiquity was long held by France. Early in the sixteenth century Budé, encouraged by the example of the Italians and influenced by two visits to Rome, built up a body of classical knowledge and produced a series of commentaries on Roman law and antiquities that gave him the reputation of being the most learned man of his time, with the possible exception of Erasmus. The line of French scholars came down through Stephanus, Scaliger, Dolet, Ramus and the learned physician, classicist and ribald Rabelais, the essayist Montaigne and the omniscient Casaubon, making the sixteenth century in France one of the most learned phases of intellectual history. Erasmus, born at Rotterdam in 1466 (or 1467), was perhaps the greatest representative of humanism as scholarship; he combined a brilliant productiveness, a many sided interest, a cosmopolitan outlook and a unique personal attractiveness. German scholarship also, from Agricola and Melancthon to Wolf and Böckh, drew its early inspiration from Italy. Except for Bentley and Porson the scholarship of England before the nineteenth century is best illumined by a consideration of the effect of Italian humanism on education.

The imprint of humanism upon formal education has been so strong as to make the expressions *literae humaniores* and "the humanities" almost synonymous with the curricula of the leading schools and universities of Europe from the fifteenth to the nineteenth century. Much of the scholarship referred to above addressed itself to the problems of education, in lectures on the classics, in the advocacy of their introduction into the schools and in the preparation of textbooks and treatises on education. A group of Englishmen, the most notable of whom were Grocyn, Linacre and Colet, men of the "new learning" as humanism was called in England, studied in Italy in the later years of the fifteenth century and on their return to England interested

themselves in the introduction of new studies and new methods into the universities and schools. Grocyn lectured on Greek at Oxford and Linacre's lectures on medicine offer a striking instance of the unexpected interests awakened by classical studies. Colet combined his inherited wealth with his humanistic ideals in the establishment of a school for boys in London, where the classics were to be studied in the modern way. This school, St. Paul's, not only trained many influential men but was taken as a model by many of the reorganized and newly founded English schools of that century and the next. Erasmus himself lectured at Cambridge, helped produce a Latin textbook for the schools and wrote a treatise on education. In the middle of the century new professorships in the classics were established at the universities and occupied by distinguished Latinists. Sir Thomas More—a typical man of the new learning although he never studied in Italy—the Fleming Vives and other humanists living in England wrote essays on education. In Germany at the beginning of the sixteenth century the old universities began to give attention to a deeper study of the classics and three or more new universities were founded directly on a humanistic basis. Still more marked was the effect of humanism on the establishment there of Latin schools, which later became known as *Gymnasia*. The famous schoolmaster Sturm at Strasbourg exerted every effort to establish the classics as the basis of education.

It cannot be said that this devotion to the classics in schools and universities retained its full vigor and fruitfulness. Humanism as a basis of education showed an inveterate tendency to degenerate into formalism. Mental training and polish such as the study of the classics offered were obtained by a few, but it became increasingly true that the great body of students derived little profit from the classics. Humanism in education has often been a fetish rather than a living principle.

Humanism furnished two of the principal roots of the Reformation—criticism of the mediaeval church and the free study of the Scriptures. But in the main it has been antagonistic to positive and authoritative religious belief. Since the reformers, reverting to the church fathers and the Bible, taught that this world is merely a preparation for the world to come, humanism could not but set itself to oppose this otherworldly spirit. When in the seventeenth, the eighteenth and the early nineteenth century the churches had become institutionalized and

fitted to secular surroundings, humanism in its turn irradiated them with its mild glow of satisfaction with this life. To Pietism, Puritanism and Methodism, and to the devoteism of the evangelicals humanism was an alien creed. It belonged rather with deism, or at least with absence of all enthusiasm in religion and a devotion to culture on intellectual grounds. Men like John Stuart Mill and Matthew Arnold best represented the survival of humanism as a refined but non-religious outlook on life, but it was also prevalent in the established churches of England and other countries. In the field of politics humanism represented this same opposition to restrictive authority. It was felt that if men are to live their lives in fulness and freedom they must be independent of the tyranny exercised either by kings or by society. The rebellion of Rousseau against the hampering bonds of eighteenth century France may in this sense be linked with the attitude of the men of the Enlightenment not only in France and Germany but also in England and America.

Despite its humane spirit humanism struck at best merely a loose alliance with the humanitarianism beginning in the eighteenth century. Except for its early enthusiasm for the classics, humanism has not been characterized by intense emotion. Revolt against injustice, cruelty and unnecessary suffering or hardship was, to be sure, a mark of the humanistic spirit, and humanitarian reforms could count on a certain amount of sympathy from persons dominated by that spirit. But the old humanistic belief in the efficacy of education checked social reforms as much as it aided them by entrusting their accomplishment to education alone. The persistent struggles that brought about better conditions of life for the mass of the people were not carried on by persons imbued with a humanistic view of life; their interests were too aristocratic and individualistic, their eyes were turned too much toward the past and upon themselves.

Humanism as a technical term and as an intellectual or moral conception has always leaned heavily on its etymology. That which is characteristically human, not supernatural, that which belongs to man and not to external nature, that which raises man to his greatest height or gives him, as man, his greatest satisfaction, is apt to be called humanism. Humanism thus means many things. It may be the reasonable balance of life that the early humanists discovered in the Greeks; it may be merely the study of the humanities or polite letters; it may be the free-

dom from religiosity and the vivid interest in all sides of life of a Queen Elizabeth or a Benjamin Franklin; it may be the responsiveness to all human passions of a Shakespeare or a Goethe; or it may be a philosophy of which man is the center and sanction. It is in this last sense, elusive as it is, that humanism has had perhaps its greatest significance since the sixteenth century. Thinkers like Descartes and Leibniz were essentially humanists however much they were forced in their efforts to solve the problem of reality to include the existence and power of a divine mind or the apparent resistance of external nature to human control. Locke, in turning away from the problems of ultimate knowledge to a test of man's ability to reach it, is thinking as a pure humanist, a student of the mind of man. His faith in the power of human nature to solve its own problems, his *Letter concerning Toleration* and his *Essays on Civil Government* exercised a strong influence on French humanist thinkers of the eighteenth century, and through Voltaire, Diderot and Montesquieu had much to do with the American and the French revolutions. Rousseau's contribution was also essentially humanistic; his conception of a law of nature was of a law of human nature and had reference to natural human conditions which, if they had once existed, might again be brought into existence by human effort. The belief in human perfectibility on which the higher reaches of the optimism and reformism of the eighteenth and nineteenth centuries were so largely built up was a humanistic belief. In Germany the amiability and enlightenment of the ideas of the romanticists, the championship of the claims of nature and freedom and self-realization by Herder and Lessing, Schiller and Goethe, formed another stage in the apostolic succession of humanistic interest in the life of man. The point of departure of Kant's critical system—that the world of experience as man knows it is the product of his own understanding—represented an essentially humanistic conception from which his immediate successors did not depart. Finally, the term humanism has been rather strictly applied to a recent school of philosophy.

The principal early rival of humanism as a way of looking at the universe was the group of ideals and institutions which were motivated by the conception of supernaturalism. But the Greeks had already found still another approach to an understanding of the world, an approach which also found its echo in the fifteenth century. They perceived that nature might be looked on

as greater than man. In the seventeenth century, as a result of the suggestions of Bacon and the discoveries of Copernicus, Kepler and Galileo, the conception of naturalism took a distinctive if not a dominant position. As students have since delved more deeply into the external world, approaching its study through astronomy, physics, chemistry and biology and using the experimental method, man has tended to lose his place as the center of all things. He has become in scientific eyes, notwithstanding the claims made for his distinctive possession of consciousness, simply one of the phenomena of observable nature. Mankind in this view appears at a definite period in the history of the material world and will in time disappear from it, leaving that world still in existence. Organic life, that of man as of other organisms and that of his mind as of his body, is a casual incident in the long history of the universe. Thus naturalism has grown up as an intellectual conception incompatible with humanism, offering a satisfactory explanation of the universe and of man's place in it, asserting the desirability of making science the predominant element in education, urging the continuous study of nature as the most useful and delightful of occupations.

Humanism may therefore be conceived of in this philosophical sense as forming, with supernaturalism and naturalism, one of three rival claimants to philosophic allegiance. It has, in reality, been a persistent element in thought, playing a varying role, as men have believed that the universe, including man, is governed by some great personality, or that it is an unconscious self-existent system of which conscious man is an inconspicuous, almost a chance part. Its dominant place has been in an intellectual climate in which man is considered the measure of the universe and the architect of his own fortunes in it.

EDWARD P. CHEYNEY

PHILOSOPHICAL ASPECTS. That the word humanism was appropriated by a famous literary and intellectual movement of the Renaissance was more or less of a historical accident, but that it should also be applied to several philosophic movements was only natural. For it is clearly a suitable term to characterize any view of the world for which humanity is the central object of interest, and as such views are numerous it must speedily acquire a plurality of senses. Their common point of departure, however, is always the human aspect as opposed to the

superhuman or the merely natural. The most fundamental formulation of philosophic humanism is still to be found in the dictum of Protagoras that "man is the measure of all things." This formula lays the sharpest stress on the relativity of all knowledge to human capacity and calls equally in question attempts to raise human knowledge to some superhuman and absolute level and to reduce it to a merely natural process. But Protagoreanism was not called humanism, as it might have been, because it was customary to misunderstand the humanist relativity of Protagoras as a form of skepticism, although it plainly proclaimed that knowledge is possible.

It was therefore left to F. C. S. Schiller to introduce humanism as a technical term into philosophy, although before him the adjective humanist had already been applied to certain tendencies in philosophy by A. Seth Pringle-Pattison (*Man's Place in the Cosmos*, Edinburgh 1897, p. 61), W. Caldwell ("Pragmatism" in *Mind*, n.s., vol. ix, 1900, p. 433-56) and Dickinson S. Miller ("The Will to Believe" and the Duty to Doubt" in *International Journal of Ethics*, vol. ix, 1898-99, p. 169-95). Schiller had at once adhered to the philosophic movement started by William James in 1900 under the somewhat unfortunate name pragmatism, a term taken over from Charles S. Peirce, and in 1903 he proposed to James to call it humanism. But when James replied that although he recognized the merits of humanism it was too late to displace pragmatism, which had already taken root, Schiller contented himself with using humanism as the name for his own variety of pragmatism. He described it as opposed in principle to both of the great attitudes which at that time dominated the philosophic field, i.e. absolutism (the attempt to assume the standpoint of the ultimate whole in describing the real) and naturalism (the attempt to describe the real in terms of a "nature" in which man was reduced to a merely natural phenomenon), and yet as in a manner mediating between these extremes. Absolutism was accused of ignoring the problems of human knowing and of overlooking the fact that the hypothesis of the possession of absolute knowledge by absolute reality in no wise vindicated or assisted human knowing, as well as of omitting to prove that the conception of absolute reality was valid. Naturalism was charged with overlooking the presence of human activity in all cognitive operations and with the (vain) attempt to interpret the whole of nature, including

man, in terms of the lower parts of total nature, with man excluded.

Thus on its critical side humanism was essentially a protest against the dehumanizing and depersonalizing procedure which seemed to characterize both the natural sciences and absolutist metaphysics. Its primary interest was in logic and epistemology, and its polemic was specially directed against the intellectualistic assumptions of the traditional logics, which systematically ignored the psychological sides of knowing and the influence of volitions, desires, emotions, purposes, bias and personality on our processes of thought. On its recognition of these neglected factors it sought to build up a positive theory of knowledge and a new logic. Thus the axiomatic "necessities of thought" of the a priori philosophies were transformed into postulates, which were rooted in emotional demands or requirements of method, but were verified and established only by their success in promoting and attaining knowledge. Such success became the test of truth, which came to depend not on a priori "intuitions" but on observable "consequences" and on the competitive "working" of rival "truth claims." Truth thereby ceased to be necessary and coercive; it became desirable and a value, denoting the success of a thought experiment and of a cognitive enterprise, while error could be conceived as a failure; and both truth and error became relative to the unending progress of knowledge and neither could any longer be conceived as absolute. Similarly the absolute antithesis between theory and practise was broken down; and although the general attitude of humanism was radically empiricist it could refuse to represent the mind as merely passive and receptive of "impressions" from the outer world. The "activism" which distinguishes it from the older empiricism reveals its affinities with voluntarism, personalism and the individualism of Warner Fite. Indeed in his latest book, *Logic for Use* (London 1929), Schiller seems to be substituting voluntarism for humanism as his own description of his doctrine.

This, however, is presumably due to the growth of other senses of humanism. If the application of the term humanism is extended from epistemology to metaphysics and general philosophy, it is evident that humanism may be taken as intermediate not between naturalism and absolutism, but between naturalism and supernaturalism, as in the *Lectures on Humanism* (London 1907) of J. S. Mackenzie, an absolutist philosopher of the idealist type, and in Viscount

Haldane's *Philosophy of Humanism* (London 1922) written with similar intent and doctrine. This second philosophic usage of humanism clearly does not involve any antagonism to absolutism. Soon afterward in America a third philosophic sense arose out of the second, when the reference of the term was further extended to religious issues. The more radical of the American Unitarian clergy gave up theism and called their purely human doctrine humanism to indicate that they no longer considered belief in a deity vital to religion. In this sense, which is finding some favor also among British secularists, humanism comes very close to what used to be called positivism. The use of humanism for what was formerly more clumsily called anthropomorphism, which is found in George Santayana's *Realm of Matter* (London 1930, p. 201), is to be welcomed as not only justifiable but as an improvement.

Finally, there is in America a movement under the leadership of Irving Babbitt and Paul Elmer More which also marches under the banner of humanism. It represents a protest against unbridled vocationalism in education and advocates a return to the old liberal education in the classical literatures. It stands for traditionalism in literary criticism and emphasizes the necessity of order in social relations, being in these respects related to the type of French thought represented in an earlier generation by Brunetière and more recently by Julian Benda. While this movement has no connection with the philosophic uses of the term it is frequently confused with some or all of them.

The net result is that there exists at present widespread confusion in the public mind about the various sorts of humanism. This will doubtless diminish in time, but it seems unlikely that philosophy will ever again give up the use of so attractive a word or that it will be found possible to reduce the surviving philosophic senses to strict unity.

Hartley Grattan (New York 1930). Keyser, C. J., *Humanism and Science* (New York 1931) distinguishes the various senses of the term.

HUMANITARIANISM. Although the word humanitarianism has had several theological meanings, the most important of which asserted that Christ was a man and not a god, its use is now wholly restricted to its social connotations. It is far from being an exact term. A humanitarian seeks to lessen suffering and increase enjoyment among all forms of sentient life. He presumably feels love or friendship toward the object of his concern; yet his strongest emotion is a kind of imaginative flinching before the

spectacle of inflicted pain. An emotional experience of direct, intense love for mankind in a mass is probably rare. Humanitarian movements have been chiefly directed toward preventing recognizable physical cruelty to men or animals or both. Where humanitarian efforts seek a positive addition to the happiness of sentient beings, it is to make the unhappy happy rather than the happy happier. Humanitarianism which appears to be leveling and democratic must not, however, be considered as synonymous with egalitarianism. It is an ingredient in many social attitudes; in the modern world it has so penetrated into diverse movements from antivivisectionism to socialism that it can hardly be said to exist in itself.

The study of humanitarianism in primitive societies can be discussed only by abandoning all notion of the word as a philosophical abstraction, as a movement, and by posing the query as to how far primitive men were cruel toward sentient beings and how far sympathetic. Savages may be very cruel and very kindly; caresses or blows depend on immediate emotion. Savages generally appear to lack the specific imaginative recoil before witnessed cruelty. When the savage acts on principle or habit he distinguishes between his own tribe and aliens. Toward the former he may feel sympathy, recognize duties of mutual forbearance and even repent cruelty inflicted in hasty passion. He regards the alien with hatred and distrust and recognizes no restrictions upon his impulses to be cruel toward alien captives in war—a rule which has notable exceptions, as in the hospitality of certain nomads. Primitive men undoubtedly achieved humanitarian reforms, although very slowly. The domestication of animals led, if only for utilitarian reasons, to solicitude for their well being. The deification of certain animals or their sacredness to some god gave them care and protection. The doctrine of the transmigration of souls, particularly when coupled with ancestor worship, also protected animals from cruel treatment. The survival of such religious beliefs in India engenders attitudes toward almost all animals incomprehensible to Europeans and has in spite of caste notions helped to keep alive a strong substratum of humanitarian feelings very useful during the present movement of passive resistance. Primitive societies employing human sacrifices came frequently to substitute animal sacrifices in their stead.

Humanitarianism emerged in the Graeco-Roman civilization as a philosophical abstrac-

tion. The Hellene distinguished sharply between himself and barbarians, slavery underlay his society as it did the Roman's and the Roman gladiatorial shows were cruel. Yet there were sporadic protests against slavery in Athens, and Seneca protested bitterly against the inhumanity of gladiatorial shows. Stoicism with its egalitarian cast and its rationalist contempt for passionate excess advanced the brotherhood of man; Marcus Aurelius urged men to love those who have offended them. Although Epicurus distrusted love he recommended and practised philanthropy—the relatively early use of the word *philanthropia* is a good indication of the development of the sentiment. Plutarch insisted on kindness to animals—not, as he was careful to state, on Pythagorean grounds of possible metempsychosis, but for its own sake as a part of the good life. In the profusion of cults in the late Roman Empire beliefs like the mysteries of Isis with their intense feeling for the union of all forms of life in death tended to mitigate the harshness of the pagan world.

The teachings of Christ as reported in the Gospels are predominantly in the direction of kindness, brotherly love and peace. Organized Christianity has from the beginning insisted on the sanctity of human life as sheltering an immortal soul and on the brotherhood of all true believers. The early church saw among its members the realization of the golden rule, a highly humanitarian aim. The church helped to keep alive the softer virtues among the cruelties of the Middle Ages and to preserve a humanitarian consciousness. Yet humanitarian writers from the eighteenth century on have been unmistakably antagonistic to Christianity, and the more extreme humanitarians have been positivistic, secularist or agnostic and not infrequently actively anticlerical. The reasons for their attitude are clear. Christianity has never wholly thrown off its early indifference to and even hatred of the flesh. In terms of Christianity suffering in this world may be a positive good; cruelty is by no means the worst of evils. Christianity denied souls to animals and therefore had little care for their welfare. The church itself early turned militant, converted unbelievers by force if necessary, refused to extend its notion of brotherhood to the heathen, tortured heretics, conducted bloody crusades. Organized Christianity has accepted—to its enemies it has seemed to promote—all sorts of social inequalities and injustices. Its temper has been resolutely pessimistic and authoritarian; it has been a stern dis-

ciplinarian, unwilling to trust men to pour themselves out in benevolence. How much of iron there is in Christianity is evident if one compares the stern Christian eschatology with the humanitarian eschatology of the cult of Isis.

Neither the Renaissance nor the Reformation concerned itself directly with lessening the total of human and animal suffering. Thomas More was genuinely moved to pity at the plight of the new poor and wished to remedy that plight by specifically humanitarian measures, and a similar impulse is evident in the work of Erasmus and other humanists. But the age was lustily or somberly passionate, neglectful of the mild and the weak.

Modern humanitarianism has its origins in the eighteenth century. The firmest believer in the guiding force of ideas can hardly refuse to see in economic and social conditions the necessary starting point of an explanation of its rise. The newly enriched middle classes largely determined the intellectual climate of the eighteenth century, although their accession to political power came somewhat later. The middle classes unlike the nobles were trained for peace and not for wars; they were not even accustomed to the blood of the hunting field. Success in trade and industry although consistent with exploitation of laborers turned ultimately on ability to cooperate with large numbers of men. Travel, which became easier and common, helped break down age old feelings of tribal exclusiveness. The middle class was so numerous that anything like a class consciousness had to rest upon a broad and general sense of the value of human life; and the necessity of attracting the support of the lower classes made an appeal to more general notions of human rights inevitable. The religious wars were over, and the national wars had not begun. Men could devote themselves to the cause of mankind, if only for lack of a more immediate cause. Under these conditions the thought of the age came to humanitarian conclusions. Utilitarianism not only found men equally capable of feeling pain and pleasure but concluded that the pleasures of benevolence were high and lasting. The rationalism of the *philosophes* found cruelty and suffering out of place in a universe as neatly ordered as the universe of Newton should be. The sentimentalism of Rousseau asked nothing better than to expend itself in pity toward the victims of an unnatural and unnecessary civilization. The most effective expressions of Christianity in the period—Pietist, Wesleyan, evangelical—sought to alleviate

suffering immediately, worked among the poor and humble and assumed functions of social service rare since the coming of the friars. The determining force in the abolition of the slave trade by England, which meant virtually world abolition, was the Tory and evangelical William Wilberforce. The fashionable and privileged world began to love or at least to feel sorry for its less fortunate fellows.

Science played a part in this development of humanitarianism. In so far as scientific progress destroyed accumulated superstitions it destroyed one of the bases of distinction between men and therefore one of the bases of domination and intolerance. The scientific attitude even in the eighteenth century was rarely without a touch of skepticism, which if it disarms for action also disarms for cruelty. Science contributed to the rationalist scheme of an ordered, just, untroubled world. But in the nineteenth century science was a blade that cut both for and against humanitarian principles. Medicine and surgery made incalculable progress against physical suffering. Applied science added greatly to the stock of human comforts. Yet the work of Malthus and Darwin continued to make fashionable and even effective a theory of the necessity for struggle which questioned the wisdom of almost all humanitarian policies. Biology seemed as hostile to the humanitarian cause as Newtonian physics had been friendly. Science as applied in the industrial revolution seemed but to put the lowly in a new plight, and as applied in war it multiplied the possibilities of inflicting death and suffering. Pessimists might well doubt whether the total achievement of science was any lessening of the fund of human misery.

Whether proportionately more individuals in the western world are humanitarian by temperament now than two hundred or two thousand years ago cannot be answered. It seems probable that a very large number of people in the modern world are incapable without extraordinary stimulation of voluntarily inflicting obvious suffering upon their fellows and upon animals. The soldiers of both sides in the World War had to be keyed up to their task; the attitude of the many whom the war left with a tragic sense of having shared in something inhuman was articulated by Henri Barbusse and Siegfried Sassoon.

The activities of the many groups which have grown up within the last century and a half to further specific humanitarian aims are impressive. The antislavery movement has almost completely triumphed; only among relatively remote

peoples does chattel slavery still exist, and European agencies are at present working to abolish it completely. Factory, sanitary and housing reforms, long urged by radical groups, have been adopted by most civilized governments and have achieved partial results. Prison reform and criminal law reform first promoted by the initiative of individuals like Beccaria, Howard and Bentham, then urged by organized welfare societies, have been taken over by governments. Eighteenth century English penal jurisprudence with its debtor's prison, its hanging for sheep stealing, its complicated penal code, its foul prisons, seemed already incredible to the nineteenth century. Social work, much of it carried on by voluntary associations, cares for the weak through poor relief, medical aid, care of the insane and feeble-minded, education and reform of delinquents, birth control, settlements, playgrounds, summer camps and by movements to encourage popular art and music. Pacifism is not only talked about and written about, as it was even in the eighteenth century, but has at least had itself embodied in special organized groups, the first step to political achievement in the western world. The Red Cross has grown from a small group seeking to improve sanitation and nursing in war to a complex society administering emergency relief all over the world in crisis situations which are defined as "acts of God."

Humanitarian movements have been directed to the special protection of children and animals. The Aristotelian classification of women as destined by nature for defenseless inferiority can hardly be accepted today; but in so far as nature and society together have conspired to put women in some respects in this category, modern humanitarianism seeks to protect them by such agencies as minimum wage laws, special factory legislation, aids to maternity and family allowances. Children are protected by child labor legislation and by societies for the prevention of cruelty to children; their welfare is assisted in many ways from youth movements to special symphony concerts for school children. The animal protection movement, strongest in England, extends to most western lands. In 1930 the Royal Society for the Prevention of Cruelty to Animals received and investigated 24,489 complaints, cautioned 21,325 people and obtained 2447 convictions for acts of cruelty to animals. Antivivisectionism is usually a part of the program of animal protection groups; vegetarianism is the last logical step in humanitarian thought and feeling in this direction.

Humanitarian purposes may cut across political temperaments and party allegiances. The humanitarian with a specific end in view may be a conservative or a liberal in politics; in England, for example, the antivivisectionists, settlement workers and sanitary reformers are to be found in political groups from high Tory to Labour. Humanitarians are frequently at cross purposes. The desire to save human lives from tuberculosis runs counter to the desire to protect animals from vivisection. The desire to make men comfortable conflicts with the desire to make them sober or chaste. Humanitarianism itself provides no way to solve such conflicts. The humanitarian with a single aim is not unlikely in a struggle to jettison the milder qualities that underlie the temperament; Robespierre himself was a notably humane person.

Humanitarian aims have always been put forward by definite groups, usually organized for the purpose. Some humanitarian organizations have abstained from political action and done their work as voluntary associations not directly concerned with the state. Others, like the various antislavery societies, have been organized largely to bring pressure on the state to embody their aims in legislation. Many of the latter societies have displayed skill in practical politics as propagandists, lobbyists, electioneers; some of them seem to outsiders to have been a trifle unscrupulous in their tactics. In the United States they can hardly be said always to have raised the level of political morality. Most of such societies combine political action with their own independent activities of education, promotion and surveillance. In all such organized humanitarian activities a tendency toward social humanitarianism is discernible in which emphasis is placed not on individual relief but on a social program. Social work is by way of becoming a profession in which centralization, efficiency and scientific method are watchwords; this may be eulogistically described as the rule of experts, dyslogistically as bureaucracy.

Humanitarianism has probably never been as fashionable, never as completely articulated with other tendencies of human thought, as in the latter part of the eighteenth century. Yet humanitarian movements gathered strength during the nineteenth century, and the humanitarian temperament seemed no less strong and no less well distributed. The post-war generation of the twentieth century is a little distrustful of the sentimental appeals of humanitarianism. Criticisms of the humanitarian approach to so-

cial problems must inevitably be affected by this unfavorable setting.

It is contended by a considerable number of critics that the attempt to solve by humanitarian methods such problems as those of crime, poverty and war is bound to fail because such methods are mere palliatives. They actually prevent the worst and logical consequences of the present social system from emerging into the light, since they gloss over and partially repair its worst failures. Soft hearted, well meaning people who help the poor and oppressed are really injuring them, since they prevent them from feeling the full force of social injustice and rebelling against it. The attitude that harshness is necessary for true reform, which has been characteristic of recent proletarian movements, is also to be found among other groups desiring radical change, like the monarchists in France and the Hitlerites in Germany.

There is the somewhat similar criticism—but a criticism based on an appeal to biology and usually made by supporters of the established order—that humanitarian aims are contrary to nature. Progress is said to be born of unlimited competition between organisms, including human organisms, and it is believed that in this competitive struggle the best and strongest survive and the worst and weakest die, leaving each generation better and stronger than the preceding one. Humanitarian efforts to aid the weak; to feed them when they would otherwise starve; to keep alive the feeble minded, the crippled, the incompetent, are regarded as a shocking defiance of a natural law of the survival of the fittest, the success of which must lead to the decadence of the race, since the artificially unfit will breed unfit descendants and lower the whole level of the race. The paradox arises that social good can only come through social evil. "Pervading all Nature," wrote Herbert Spencer in a protest against poor relief, "we may see at work a stern discipline which is a little cruel that it may be very kind." This appeal to a nature which disapproves of humanitarian intervention is in its extreme as logically absurd as certain forms of humanitarian belief, such, for example, as vegetarianism. All surgery is an interference with nature. Moreover modern biology is not so sure about the ways and means of the survival of the fittest as was the nineteenth century; and modern political thought has begun to assert its right to formulate its own conclusions on such problems without wholesale borrowing from any of the physical sciences. The point of view sketched

in this criticism of humanitarianism, however, has even now great influence on both the learned and the ignorant and presents a problem by no means solved. The sterilization of the feeble-minded, shocking to humanitarian sentiments, may be an acceptable procedure—unwillingness to go further in this direction is inspired less by humanitarianism than by an uncertainty as to who are biologically fit as well as to the laws of heredity.

The ethical criticism of humanitarianism, especially associated with Irving Babbitt and the new humanists in the United States and with Seillière in France, is no doubt largely a matter of definition but is more than a logomachy. Humanitarianism, modern democracy, nationalism, imperialism and all typically modern politics and morals are traced by Babbitt to the eighteenth century and especially to Rousseau. Christianity and humanism agree that men have two natures, good and bad, human and animal; that each man is torn between these natures; and that this civil war must end in the triumph of man's better nature if he is to be a satisfactory member of society. His better nature will triumph only through discipline; only through a religious, moral and aesthetic control exercised partly at least by external authority and closely dependent on tradition. Humanitarianism, on the other hand, denies this inevitable dualism within the individual. It maintains, following the sentimentalists, that men are naturally good or, following the rationalists, that they are naturally reasonable. It encourages the individual to pour out his feelings uncontrolled, to take his desires as measures of what he can and should attain. It puts a high value on sentiment, a low value on genuinely critical thought. Babbitt declares that civilization needs discipline, which humanitarianism cannot supply, and that humanitarianism is a dangerous guide because it is optimistic. Babbitt's moral paradox, which is curiously parallel to Spencer's scientific paradox, is that happiness can be attained only through pessimistic distrust.

Humanitarianism, however, is perhaps not in quite so bad a plight as the foregoing criticisms would imply. Few of the opponents of humanitarianism as a group movement and a faith would like to see the number of individuals of humanitarian temperament seriously diminished. The scientists and moralists who defend discipline recoil from cruelty. Part of civilization is specifically a humanitarian conquest; doubts may be entertained about capital punishment but none

about the rack. Much of the opposition to humanitarianism is abstract; those who find the humanitarian approach to life too soft, colorless or unimaginative can hardly lead a ruthless free-booting existence.

The palliative element in humanitarian corporate efforts has been defended as an asset. What to the proletarian or nationalist in revolt may seem to be a sidetracking of human effort no doubt seems to the conformist, to the defender of things as they are, a useful means of social adjustment. To such people humanitarianism is often a happy prophylactic against revolution and unrest. Humanitarian societies working by propaganda, lobbying and all the other ways of political groups toward a specific end, such as the abolition of slavery or child protection, have been successful. Success arises partly because of effective organization but also because humanitarianism has in itself a high publicity value; an issue may be subtly brought home to the selfish individual if it can be made to touch him as one of all mankind. Men are curiously unable to act in concert for avowedly selfish purposes and do not commonly do so. Their ideas and expressed motives are very often of a humanitarian character which seems to contribute notably to their spread.

For some people the humanitarian attitude is capable of an emotional codification into a religion. Such was the aim of Comte in his later years, and positivism may be defined as a religion with scientific determinism as its dogmatic basis and an orderly love of mankind as its emotional basis. Although his humanitarian religion has failed to make much progress and has lost ground since the World War, it may eventually prove to be a suitable faith. But as a religion humanitarianism seems to suffer from the defect that it is based on a negative aversion from suffering rather than on a positive search for pleasure. It is unavoidably a religion for the weak. The psychological roots of the humanitarian sentiment lie among the compensating mechanisms whereby the individual makes up for his bewilderment in this chaotic world. More than humanitarianism is necessary, for the great adventures both of thought and of emotion lie beyond philanthropy.

HUMBOLDT, ALEXANDER VON (1769-1859), German natural scientist and human geographer. After studying public finance, technology and the natural sciences at Frankfurt on the Oder, Göttingen, Hamburg and Freiberg and serving as a mining engineer for the Prussian government, Humboldt between 1799 and 1804 made scientific expeditions through Central and South America, the extensive accounts of which laid foundations for the sciences of physical and economic geography and meteorology. He initiated the procedure of correlating the distribution of plant life with altitude and temperature and made notable researches on tropical agri-

culture and on the production of precious metals in Mexico. His calculation of the amount of gold and silver exported by America to Europe from 1492 to 1803 furnished the international money market with a basis for financial operations. He also recorded the languages and described the distribution of the peoples and the cultures of Central and South America, reckoned the density of population and studied the influences of the natural environment and economic conditions upon social and political life. His travels were instrumental in encouraging German colonial expansion. Humboldt's extensive and diversified contributions to science led him to be widely hailed during his lifetime as one of the most learned and influential of the men of his period.

HUMBOLDT, FRIEDRICH WILHELM VON (1767-1835), German statesman and savant. Wilhelm von Humboldt, the brother of Alexander von Humboldt, was influenced in his philosophy chiefly by the works of Kant. He formulated the educational program of German neohumanism in his essay *Über das Studium des klassischen Altertums* (1793). Out of his close friendship with Schiller and Goethe developed monographs on aesthetics, psychology and the theory of education. After travels through France and Spain, during which he became interested in philology, he was appointed Prussian minister plenipotentiary to the papal court in 1802. As minister of public worship and education in 1809 and 1810 he together with Nicolovius, Sövern, Schleiermacher and others reformed the Prussian state educational system along the lines of the educational ideas of the German classicists and neohumanists. Politically this reform ranks as a part of the Stein-Hardenberg reform of Prussia, which incorporated the ideas of the

French Revolution. The general education of man became the guiding principle in all stages of the educational system, as sharply opposed to the trade and class training of the period of Enlightenment. Humboldt formulated a curriculum in which the elementary school used the Pestalozzi method, the *Gymnasium* laid considerable emphasis upon Greek and the university had the general scientific framework of the philosophy of the speculative idealists—Fichte, Schelling and Schleiermacher. The establishment in 1810, in the midst of the privations of war, of the University of Berlin with its principles of freedom of research and freedom of teaching was Wilhelm von Humboldt's greatest achievement.

In his political philosophy Humboldt remained a liberal all his life. But this liberalism went through profound transformations under the influence of contemporary events. His *Ideen zu einem Versuch, die Grenzen der Wirksamkeit des Staates zu bestimmen* (1792) was still entirely individualistic and almost hostile to the state. His aesthetic liberalism of this period would confine the state merely to the exercise of protective and legal functions in order to insure the attainment of a higher end, free and beautifully developed individuality. Later influenced by romanticism, Humboldt attached greater significance to the concept of the supra-individual and historically conditioned nationality. Like Fichte he conceived the individual nationality to be only a segment of the universal spiritual and divine life and thus justified nationality only as a particular and characteristic expression of humanity. Even as minister of education he considered the state in strictly intellectual matters only as the "vicar of the nation." In his two memoirs concerning the German (1813) and the Prussian (1819) constitutions he, like Baron vom Stein, advocated a liberalism preserving the historical traditions and the individual life of the local states, provinces and regions. He endeavored to "fit the constitution closely to the genius of the national character." Although he admitted certain fundamental rights of the individual he did not, as in the atomistic liberalism of the French revolutionaries, derive the state from the isolated wills of individuals. Nor did he, like the conservatives, wish to revive the old feudal estates. His program called for a "traditional liberalism" with the regional self-governing bodies taking part, through their representation in district, provincial and general estates, in the old monarchical bureaucratic state. These en-

deavors were frustrated by the reaction arising in 1819.

HUME, DAVID (1711-76), English philosopher. Hume's life may be divided into three stages: youth, maturity, repose. After an unsuccessful trial of a business career he retired to France, where in three years, from 1733 to 1736, he wrote his most important work, *A Treatise of Human Nature* (3 vols., London 1739-40). During this period he lived in almost complete seclusion and considerable poverty. From 1738 to 1762 he composed a variety of works including the *Inquiry concerning the Principles of Morals* (London 1751), *Essays Moral and Political* (2 vols., Edinburgh 1741-42; 3rd ed., 1 vol., 1748), the *Political Discourses* (Edinburgh 1752) and a *History of England* (8 vols., London 1763; new ed. 1778). From 1763 to 1769 he acted with considerable success as secretary to Lord Hertford, the British ambassador at Paris. The third period may be said to begin in 1769 with his retirement, a comparatively wealthy man, from the diplomatic service and his return to Edinburgh, where he remained the acknowledged center of the intellectual life of the city until his death.

Hume's fame today rests almost entirely upon his writings on metaphysics and theory of knowledge; that is to say, upon the *Treatise*. The conception of human nature which emerges from his treatment of the subject in this work largely determines his attitude to the social sciences. Hume is definitely the most "psychological" of the eighteenth century philosophers. He holds that successfully to solve the various problems of human life and human society it is necessary to understand man's nature, and the methods which he suggests for the attainment of this understanding are very similar to those which would now be adopted by a psychologist who still retained a belief in the efficacy of introspec-

tion. Hume in fact was the first to believe that the study of human nature could be made a science, the foundations of which he endeavored to lay. His conclusion that the human mind consists of impressions and ideas associated in various ways may be regarded as the starting point of his treatment of ethics, politics and economics.

In ethics it led him to adopt a utilitarian position, which the more famous utilitarians of the first half of the nineteenth century were to develop rather than to modify. Action, he held, is good in so far as it promotes the happiness of society. Yet, although he regards happiness as the only desirable end, his hedonism is universal rather than individual. Men, he teaches, are endowed with a sentiment of humanity by virtue of which they are led to desire not only their own good but that of society. The human heart is in fact so compounded that it cannot be indifferent to the public good. Since one's duty is to promote the good of society, the so-called moral obligation is not absolute but conditional. The command that men should do their duty for duty's sake irrespective of its consequences seems to Hume an outrage to the intelligence. In Hume's view virtue becomes the habit of acting in a way of which other people approve, because it conduces to their well being. Thus the virtues are envisaged by Hume as kindly and genial; condemning as worse than useless "mortification, self-denial, humility, silence, solitude and the whole train of monkish virtues," he commends in their stead "gentleness, humanity, beneficence, affability; nay even, at proper intervals, play, frolic and gaiety." Hume's ethical doctrine is a perfect expression of the enlightened humanism of the eighteenth century seen at its best, devoid as yet of the somewhat graceless and unattractive logical extremism to which Bentham was subsequently to push it.

Hume's political views, like his ethics, are dominated by the principle of utility, which leads him to regard the promotion of human happiness as the object of political thinking and the touchstone of political action. His political theory begins with a criticism of the social contract theory, which was still dominant when he began to write. The social contract is criticized, first, on the ground that there is no historical evidence for its occurrence; secondly, because it is in any event unnecessary to presuppose that for which there is no evidence. The social contract theory based the duty of obedience upon the obligation to keep a promise. Hume derives

the duty of obedience from the fact that, were it not recognized, society would be impossible. Yet society is an indispensable condition of human happiness, so much so that man cannot be conceived at any time to have lived otherwise than in some sort of community. To say therefore that society rests upon consent is to say merely that men consent to live in the only way in which the possibility of happiness can be guaranteed to them. The ideas of justice, property, right and obligation are all derived from this consent.

Hume's application of the principle of utility issued in a conservative attitude toward practical politics. He repudiates Locke's attempt to base the right of property upon labor and establishes it upon habit and association. *Salus populi*, he holds, *suprema lex*; and, although he admits that insurrection may sometimes be justified, in practice he finds that the principle of utility operates strongly on the side of obedience and security.

His contribution to economics consists chiefly of the attempt to relate all phenomena to their roots in human nature. "Everything in the world," he asserts, "is purchased by labour, and our passions are the only causes of labour." Thus utility, the utility of a piece of work in satisfying men's passions, is the core of his theory. This does not mean, however, that he ignores the claims of labor. On the contrary, he holds that it is the business of the state to guarantee to all men the right to enjoy the fruits of their labor; all should have the necessities, most the conveniences of life. Great differences in wealth are moreover a source of weakness to the state. There is a distinct flavor of socialism in Hume's attitude toward the rights of labor, just as there is a strong conservative bias in his attitude toward property. In general, however, the views of Hume foreshadow those of the philosophic radicals, and his insistence on the overriding principle of utility and the universality of his application of it constitute the point of departure for the utilitarian thinkers of the nineteenth century.

Of Hume's more technical economic contributions the most important is his theory of international trade, the basis of the later classical doctrines of Thornton, Ricardo and J. S. Mill. Hume applies the quantity theory of money to the universe of countries engaging in commercial dealings with one another and treats as its corollaries the propositions that excessive trade balances cause international specie flows and that specie stocks are distributed among coun-

tries in a more or less automatic fashion. Although money is "none of the wheels of trade," Hume believes that a gradual increase in circulating media would be advantageous since in the interval of price readjustment real wages and productivity of labor would be increased. He protests also against the view that the rate of interest is dependent upon the quantity of money; he considers the important factors to be the demand and supply of capital or loan funds and the rate of profit, holding, however, that both profit and interest rates are a function of the stage of development reached by commerce.

In his own day Hume was chiefly celebrated as a historian. His dominating characteristic, intelligence, is nowhere better exemplified than in his history. Before Hume historians had tended to be moralists or memoir writers; their object had been to point a moral or to adorn a tale. Hume was concerned simply to tell the truth; gracefully, it must be agreed, but never conceding so much to grace of language or picturesqueness of subject matter as to weaken his overriding determination to say exactly what had happened exactly as he conceived it to have happened. The facts available in Hume's time were limited, and for this reason his history is little read today; its real importance consists in the fact that Hume returned to the conception of history as a record of objective fact, from which since the days of Thucydides his predecessors had shown an increasing tendency to depart and to which his successors were to endeavor with greater or less success to conform.

HUNG HSIU-CH'ÜAN (1813-64), Chinese revolutionist. Hung led the Taiping rebellion against the Manchu dynasty in the middle of the nineteenth century. He was born near Canton and until the age of thirty was an obscure pedagogue who had failed in the civil service examinations. Some contacts with Protestant missionaries, combined with visions which first came during a severe illness, led him to lay the foundations of a religious sect which combined in bizarre fashion Christian and Chinese beliefs and practises. Its early strength was in the province of Kwangsi. Here, largely under other

leadership than Hung's, it became a religious political organization seeking to substitute itself for the ruling dynasty. Serious fighting began about 1850. After working widespread devastation in south and central China, by the middle of 1853 the rebels had captured Nanking, where Hung ruled as the head of the would be dynasty. He showed little or no skill in administering or retaining his conquests; the fighting was done by subordinates. The rebellion was finally crushed by Chinese forces with some foreign assistance. Shortly before the fall of Nanking Hung committed suicide. Some of his followers, migrating overseas, helped in the preparation of the revolution which set up the Chinese Republic in 1911-12.

HUNGER STRIKE. The hunger strike has been adopted and developed in many countries as a method of protest against governmental authority, especially by certain types of political prisoners. Devices of a similar nature, although individual and non-political in character, are well known in the Orient. The practise of "fasting on one's enemy," particularly on his doorstep, for the purpose of humiliating him or as a means of revenge by inconvenient martyrdom is an institution of ancient date in Japan. In India the similar device of "sitting dharna" has been resorted to from time immemorial by suppliants, penitents and persons determined to compel attention to their grievances. The hunger strike as a modern political device was probably first used in Russia by exiles and political prisoners under the old regime as a last desperate resort in securing some amelioration in their treatment. As early as 1889 forcible feeding was used on women hunger strikers in the Kará prison.

The hunger strike attained world wide celebrity, however, in 1909 through the action of the militant wing of the English women suffragists led by Mrs. Emmeline Pankhurst and her daughters. Members of the Women's Social and Political Union had for some years been imprisoned for such offenses as causing disturbance and damage and annoying cabinet ministers. In July, 1909, Miss Marion Wallace Dunlop was sentenced to one month for printing on the wall of the House of Commons a clause from the Bill of Rights. In protest against being treated as a common offender instead of as a political prisoner

she started a hunger strike. The prison officials were unprepared for this novel weapon, and the prisoner was released after a fast of ninety-one hours. Her action opened a chapter of extraordinary events. The hunger strike became at once the accepted—almost the obligatory—weapon of the insurgent suffragists protesting against their status as ordinary convicts and it was employed by unbroken relays of women prisoners until 1914. Many hundreds of women suffragists and a few men prisoners sentenced in connection with the movement during those five years endured the hunger strike.

The increased and large scale use of the hunger strike forced the authorities to devise some procedure which would permit them to keep the prisoners alive and in jail through the period of their sentence. Every possible means was tried to overcome the resistance of the women: persuasion, medical argument, threats, cajolery and sentimental appeal. Special food and drink, particularly appetizingly and delicately served, were sent into the cells. All efforts of the kind failed. In September, 1909, the authorities adopted the device of forcible feeding. Milk and meat juices were regularly fed to the hunger strikers through the gullet or the nostrils by means of a tube. The process was invariably painful and frequently resulted in temporary and even serious injuries. Unremitting attacks in Parliament and a memorial signed by over a hundred doctors who protested against the serious physical consequences of the procedure failed to stop the practise of forcible feeding. But the hunger strikes continued despite the new method. At one time several hundred women were being forcibly fed in English jails. The prisoners, many of them very young, obeyed the discipline of their union and kept up their resistance. In March, 1913, the Asquith government carried the Prisoners' Temporary Discharge for Ill-Health Bill (nicknamed the Cat and Mouse Act), which permitted the authorities to release for a few days any hunger striker judged to be in danger of collapse. Women set free under the act were hidden and usually succeeded in remaining at liberty. Mrs. Pankhurst, however, was released and rearrested ten times and her daughter Sylvia nine times under one sentence. None of the prisoners was allowed to die in prison either as a result of the hunger strike or of forcible feeding. At the outbreak of the World War a truce was called, and the passage in 1918 of the Franchise Act embodying the principle of woman's suffrage settled the prob-

lem of the hunger strike as far as the suffragists were concerned.

But the device had by that time been adopted by the Irish nationalists, who ultimately developed and exhibited its most remarkable forms and results. A few Irish women suffragists had undertaken the hunger strike, notably Mary Leigh and Gladys Evans, who in 1912 at Mountjoy prison had been forcibly fed for nearly six weeks. In 1913 James Connolly, the poet, jailed for his part in the great Dublin strike, was released after a fast of eight days and in 1915 Francis Sheehy-Skeffington, imprisoned for antiwar speeches, was released under the Cat and Mouse Act after a similar length of time. In 1917 Thomas Ashe and several others, imprisoned in Mountjoy for sedition, went on a hunger strike and were forcibly fed. Ashe died as a result of the feeding and was accorded an impressive public funeral. His death put an end to forcible feeding in Ireland. Thereafter the government resorted to the Cat and Mouse Act, but the effect was to make sentences of imprisonment meaningless. Between November 15 and 21, 1917, over one hundred hunger strikers were released from various prisons. Increasing Sinn Féin activities finally forced the government to announce in Parliament on November 24, 1919, that hunger strikers would thereafter be forced to "take the consequences." The policy, however, was easier to announce than to apply. In 1920 members of the Irish Republican party in prison resorted to the strike and were set free. As the British suffragists demanded treatment as political prisoners, so these Irish hunger strikers demanded treatment as prisoners of war. In the same year a general hunger strike of Irish political prisoners in London secured the release of the whole body. In some cases the fast covered three weeks. Finally the government was forced to apply its ruling literally. In August, 1920, Terence MacSwiney, lord mayor of Cork, and eleven other Republicans imprisoned for sedition went on a hunger strike. Three of the twelve died of starvation in the Cork jail. MacSwiney was removed to Brixton Prison, London, and died there on October 25 after an amazing fast lasting seventy-four days. This record has been surpassed in modern times only by Joseph Murphy, who died during the same hunger strike after a fast of seventy-six days. These deaths ended hunger striking activities in Ireland for a while; and on November 13, 1920, all hunger strikes ceased on the order of Arthur Griffith, acting president of Sinn Féin.

After the establishment of the Irish Free State, however, the hunger strike was again adopted by Republican men and women in 1922 and 1923 as a weapon in their war on the new state. In November, 1922, Mary MacSwiney, a sister of Terence, was imprisoned and went on strike. Thereupon Annie, another sister, introduced a new device by going on a sympathetic hunger strike before the gates of the prison. Among the strikers in 1923 were some notable Irish women Republicans, including the Countess Markiewicz and Maud Gonne McBride. The Irish government was forced to advocate the English method, and on May 3, 1923, the Dail decided accordingly. The last mass hunger strike, which began in October, 1923, and was participated in by several hundred Republicans, was called off as a failure after having continued for six weeks and resulted in two deaths. The longest strike by a woman prisoner (forty-three days) is recorded in connection with this episode.

In the United States the first case of forcible feeding in connection with a hunger strike was probably that of Mrs. Ethel Byrne, a sister of Margaret Sanger, who was sentenced in January, 1917, to one month in the workhouse for operating a birth control clinic. Her condition became so serious that the governor pardoned her on the promise, given for her by her sister, that she would cease her activities. In the American woman's suffrage campaign hunger striking was tried on a more restricted scale than in England. In October, 1917, Alice Paul, the leader of the National Women's party, who had taken part in the English militant suffragist activities, was sentenced with several other women to seven months' imprisonment for picketing the White House. She went on a hunger strike which lasted twenty-two days and was forcibly fed. Several other suffragists also struck and were similarly fed. So great, however, was the public outcry that the treatment was abandoned after having been tried on a few prisoners. Between 1917 and 1919 more than a hundred American suffragist prisoners went on hunger strike. All were released after fasting a few days. Conscientious objectors confined in American military camps during the war used the hunger strike several times to secure better treatment; the most successful strike was probably that at Fort Riley in 1918, which lasted thirteen days. Nicola Sacco, whose conviction in Massachusetts for first degree murder was widely attributed to his anarchistic views rather than to the evidence pre-

sented, went on a hunger strike in February, 1923, while his appeal for a new trial was pending. He was forcibly fed after thirty days and abandoned the strike on the plea of his wife.

In the prolonged agitation of Indian nationalists Gandhi has subjected himself to fasts of differing lengths, not in prison and not in protest against executive authority but as self-inflicted penance for the failures or misdeeds of his followers and as a means of forcing them to accept his proposals. Indian nationalist prisoners have not often adopted the hunger strike, but it has several times been resorted to by accused Indians awaiting trial in conspiracy cases. In the affair of the Lahore conspiracy (1928-29) eight Indians went on a hunger strike. Jaitendranath Das died after sixty-one days and the others abandoned the strike.

The principal force of the political hunger strike, as of its oriental prototypes, lies in the appeal to the individual conscience, to the unwillingness to be the cause of a person's death. Not only is this true in the case of the suffragists, who had obviously committed no crime deserving the death penalty, but even the Irish Republican strikers felt that while the government might not hesitate to shoot them out of hand it would shrink at the idea of letting them die by inches. The Russian government, accustomed to a treatment of political prisoners which frequently drove them to suicide, yielded several times before the prospect of causing lingering deaths by starvation. Furthermore behind the conscience of the individual official stood the conscience of the nation, an important factor in a democracy and one which all the hunger strikers aimed to reach. It was important to put their suffering before the eyes of the nation, not only to secure their own release but to emphasize their devotion to their ideal and its consequent apparent importance. Especially in the latter days of its use the hunger strike required willingness to suffer and possibly even to die for one's ideal. Records of the death of at least three ordinary criminals in England as a direct or indirect result of forcible feeding indicate that hunger striking was not unknown among such prisoners. But the stake was almost always too great for non-political offenders and the chances of success were practically nullified through the absence of any organized external protest based upon some ideal or moral ground. More and more the hunger strike tended to become a game of bluff and endurance between officials and prisoners. The officials apparently never wel-

comed the death of the strikers, but a gradual blunting of the official conscience seems apparent. To this end a variety of factors may have contributed, including the shift from a preponderance of women to men strikers, the severity of the Irish civil war, the condemnation of the strike as a form of suicide by elements in the Catholic church and the growing familiarity with the strike. Furthermore the early abandonment of forcible feeding in Ireland left the authorities with only two alternatives—release of the prisoners or resistance to the strike—and rendered more evident the serious implications for law and order which followed from any easy yielding. These anarchic tendencies of the hunger strike, coupled with the constant threat of the Republicans to peaceful government in the Free State, probably aided in creating a public opinion which acquiesced at least tacitly in the policy of resistance to the hunger strikers.

HUNT, FREEMAN (1804-58), American business journalist. Hunt worked at the printer's trade in his youth and later successfully published and edited four magazines of general interest. In 1839 he started the *Merchants' Magazine*, which he edited until his death, thus laying the foundations of modern business journalism in the United States. Hunt endeavored to professionalize trade and to change the conception of the merchant from a money maker who read only his ledgers to a business statesman who combined a "vast comprehensiveness" with "a most minute grasp of details" (*Lives of American Merchants*, 2 vols., New York 1856-57, vol. i, p. iii). He believed that a business education must include "the study of the resources of nations . . . the processes of production, and the Laws of Wealth" (*Wealth and Worth*, New York 1856, p. vii). The *Merchants' Magazine* published general theoretical articles on such subjects as the tariff, credit, money and banking, economic descriptions of various regions, dis-

cussions of commercial law, navigation, trade regulations and treaties and a large body of statistics of industry, commerce and banking. These statistics, the chronicle of commercial developments and in some measure the reports on trade regulations were issued at regular monthly intervals; they made currently available for the first time a body of facts upon which a broad business policy could be based. The magazine was responsive to the changing needs of business and reflected the shift in emphasis from mercantile to industrial and financial enterprise. It merged in 1871 with the *Commercial and Financial Chronicle*, which had been issued for some time as a weekly supplement to the *Merchants' Magazine*.

Hunt severely criticized merchants for sharp practises and still more for narrowness of vision. He held commerce to be a branch of statecraft, since the interests of merchants "have become a chief concern of statesmen . . . afford a leading subject of the legislation of States, and fill the largest space in the volumes of modern jurists" (*Lives*, vol. i, p. iii). The business man should be equipped scientifically to perform his broad function; and Hunt regretted in 1856 that he could not then prepare a system which "would embrace a code of business ethics, . . . the rationale of business management, and a course of business education" which "might be studied with advantage by the Merchant's Clerk, just as the law student, or the medical student, studies the elementary books of his profession" (*Wealth and Worth*, p. vi, vii). The men of commerce whom Hunt set forth and commemorated in his writings were principally the New England merchants of Salem and Boston. These men he adduced as "evidence that the 'Merchant' may also be a gentleman and a scholar, as well as an honest and kind hearted man" (*Lives*, vol. i, p. vi). It was the traditional merchant prince whom he thought to serve; but the development of business enterprise, facilitated by the data which he himself published, led to the rise of a new business type, the modern financier.

HUNTER, SIR WILLIAM WILSON (1840-1900), British historian and statistician. Hunter was born in Glasgow and after graduating from Glasgow University entered the Indian civil

service in 1861. He arrived in India in the following year and soon showed a gift for collecting materials from old records, as revealed in his *Annals of Rural Bengal* (3 vols., London 1868-72; 7th ed., 1 vol., 1897). In 1869 Lord Mayo, the governor general of India, placed him on special duty "to submit a comprehensive scheme for utilising the information already collected, for prescribing the principles according to which all local gazetteers are in future to be prepared, and for the consolidation into one work of the whole of the materials that may be available," and in 1871 he became director general of statistics to the government of India. Thus Hunter began an undertaking for India, similar to the *Statistical Account of Scotland* of Sir John Sinclair, which resulted in a huge statistical survey, numbering 128 volumes, of the geographic, social and economic conditions in India. He not only supervised the work of the editors of local gazetteers but also undertook to write on the provinces of Bengal and Assam. Hunter's chief importance, however, is not as a statistician but as a historian who had an unrivaled gift for the collection of many facts regarding Indian history which few have until recent years taken the trouble to examine. His *A History of British India*, of which only two of the projected five volumes appeared (London 1899-1900), and his lives of Lord Dalhousie (Oxford 1890) and Lord Mayo (Oxford 1891) are important contributions to the study of the history and administration of British India.

G. FINDLAY SHIRRAS

Consult: Skrine, F. H. B., *The Life of Sir William Wilson Hunter* (London 1901).

HUNTING has from the earliest times to the present been a feature of almost every culture of which there is record. In palaeolithic times hunting furnished the basis of the food supply, as is shown by deposits of broken and gnawed bones of wild animals and by engravings and paintings on cave walls depicting animals wounded by the spearhead of the hunter. Hunting preceded domestication and agriculture as the main source of the food supply; as Thurnwald has shown, peoples who adopt pastoral life or agriculture do not revert to the hunting stage, although there may be a revival of hunting.

The concept of a hunting or hunting and fishing culture stage is both legitimate and convenient. In many instances, however, a classification on this basis is difficult, because many hunters supplement their food supply by stock

raising or agriculture; and, conversely, practically all pastoral or agricultural peoples secure some food by hunting. Thus the Pueblo Indians of the southwest of the United States depend almost entirely upon agricultural products but do some hunting, mainly for rabbits. The northern Iroquois, on the other hand, although they had developed agriculture to a high point, supplemented this diet to a considerable extent by the flesh of wild game and doubtless could have subsisted on game and fish.

The principal means of securing wild game are throwing devices, the bow and arrow, traps, drives and simulation. Throwing devices include the throwing stick and its modification, the boomerang, which was used in ancient Egypt, southern India, Australia and in the southwest of the United States; the spear, used in the upper palaeolithic period and although widely distributed most important in Australia, Oceania and Africa; the bolo, used by the Eskimos and on the pampas of South America; and the harpoon, found in early and transitional Mediterranean cultures, on the Andaman Islands, among the Eskimos and southward along the Pacific coast to Central America and Guiana. The bow and arrow, probably not used during the palaeolithic period, were almost universal among the preliterate peoples with the exception of Australia and perhaps parts of Polynesia. They were used in all of the historical cultures and remained until the introduction of gunpowder the most effective weapon of mankind. The most widely distributed forms of trap are the dead-fall, the snare and the pit. The use of birdlime was most general in Oceania and the early Mediterranean culture and was restricted to the Old World. The drive has been employed in parts of aboriginal North America and in South Africa; the Eskimos supplemented it by the use of dogs. Attracting the animal by imitating its call was a device used by the Eskimos; it was found also in the woodland area of northern North America and in Siberia. Disguise by the use of seal skin, wolf skin or caribou antlers is also found in these regions.

In the hunting cultures there is no pottery save in areas peripheral to agriculture, in parts of Alaska and in the transitional culture of the Mediterranean region. There is no elaboration of domicile except on the northwest coast of North America, where the assured supply of salmon favors higher culture. Although property in land is usually absent it has been found in the hunting cultures; Speck, for example, found a

recognition of family hunting domains among the Algonquin hunters, and Davidson charted hunting territories in Australia. A hunting culture seldom shows the elaboration and intensification of traits frequently found in agriculture, such as a priesthood, kingship or social hierarchy. Even in primitive society, however, hunting is not a mere economic enterprise; it is often fraught with adventure, calls forth emulation and courage and wins prestige. It has been primarily an activity of men only. Magical and religious motives influence the hunt and frequently supernatural tabus are observed lest the entire community suffer.

The metaphor and imagery of the Old Testament show little interest in hunting and practically no knowledge of it, for the people in Biblical times had become pastoral or agricultural. In ancient Egypt, Babylonia and Assyria, however, hunting was a pastime of kings and nobility. In Greece and Rome hunting was a pastime for the wealthy classes. A fresco at Tiryns of about 1500 B.C. shows hunting dogs wearing collars in pursuit of a wounded boar. Xenophon, Plato and later Arrian refer to the pastime of hunting. Xenophon considered it a valuable training for the demands of military life; in his day the hare was run into nets stretched across courses which it was expected to take. When Arrian wrote about five hundred years later the hare was run down in the open—a change probably due in part to the importation of swifter hunting dogs from Gaul into southern Europe. Arrian's detailed description of Celtic hunting reveals close resemblance to the present English pattern; there was scouting to locate the hare, participation by many in the hunt, each with his own hound, and a master of the hunt. During the period of the Roman Empire, particularly in North Africa and Asia Minor, there were hunts of bear, elephant, lion, tiger, leopard, bison and rhinoceros with the use of pits, traps and nets.

Fowling by sling, bow and arrow, throwing stick, net and torch was a favorite sport in classical times. The owl was used to decoy small birds, and birdlime attached to a rod was a favorite device for taking birds from the low limbs of trees. Falconry was practised by the Greeks at least by the fourth century B.C.; it was known to the Romans three centuries later and to the Anglo-Saxons, although after Roman times it practically disappeared from Europe. The Byzantine Demetrius gives an intimate account of the art of hawking. Tradition ascribes the reintroduction of falconry into Europe to the

emperor Frederick Barbarossa and his grandson Frederick II; a portion of an unfinished book on the subject by the latter was printed in 1596 together with a work on falconry by Albertus Magnus. By the fourteenth century, when *Le art de vénerie* by one William Twety appeared (about 1328), falconry had become the most popular sport in the British Isles. *The Boke of Saint Albans* (1486), which for a long time probably exceeded in circulation any other printed work except the Bible, describes the hawk for each social class—for duke, earl, baron, knight, squire, yeoman, priest and clerk. By the early eighteenth century falconry had almost disappeared as a national sport in the British Isles.

The red deer was the animal most often hunted in England from the time of William the Conqueror; there were no restrictions upon the hunting of it until Tudor days, when much of the land had been brought under cultivation. After the war between Charles I and Parliament wild deer could be found in only five localities. During the protectorate the raising of foxhounds or harehounds became common throughout the country; the land was overrun with foxes, which killed many lambs, and there were communal as well as private fox hunts. The organization of fox hunting clubs dates from the time of Charles II, when the Charlton Hunt was established; about a hundred years later subscription packs were formed. Riding with the hounds attained its present popularity in England in the nineteenth century. The extent of the practise is indicated by an estimate made about 1900, which found the number of hunting horses in Great Britain to be 200,000 with 67,000 men attending them. Fox hunting has developed only in countries with a large British population and among people of British heritage. Of the eighty-six packs of foxhounds used outside the British Isles in 1925 there were forty-seven in the United States, sixteen in New Zealand, ten in India, four in Australia, four in east and South Africa, three in Canada, one in China and one in Palestine. Wherever it has developed, hunting with horse and hounds has been limited to the aristocracy and the leisure, sporting and military classes. Until recently it was restricted to the landed gentry; in Great Britain it is still a matter of considerable social prestige.

In the New World game was abundant at the time of settlement; and hunting, which until recently occupied a prominent place in the life of the people, was the theme of the popular novels of James Fenimore Cooper. The move-

service in 1861. He arrived in India in the following year and soon showed a gift for collecting materials from old records, as revealed in his *Annals of Rural Bengal* (3 vols., London 1868-72; 7th ed., 1 vol., 1897). In 1869 Lord Mayo, the governor general of India, placed him on special duty "to submit a comprehensive scheme for utilising the information already collected, for prescribing the principles according to which all local gazetteers are in future to be prepared, and for the consolidation into one work of the whole of the materials that may be available," and in 1871 he became director general of statistics to the government of India. The Byzantine Demetrius gives an intimate account of the art of hawking. Tradition ascribes the reintroduction of falconry into Europe to the

emperor Frederick Barbarossa and his grandson Frederick II; a portion of an unfinished book on the subject by the latter was printed in 1596 together with a work on falconry by Albertus Magnus. By the fourteenth century, when *Le art de vénerie* by one William Twety appeared (about 1328), falconry had become the most popular sport in the British Isles. *The Boke of Saint Albans* (1486), which for a long time probably exceeded in circulation any other printed work except the Bible, describes the hawk for each social class—for duke, earl, baron, knight, squire, yeoman, priest and clerk. By the early eighteenth century falconry had almost disappeared as a national sport in the British Isles.

The red deer was the animal most often hunted in England from the time of William the Conqueror; there were no restrictions upon the hunting of it until Tudor days, when much of the land had been brought under cultivation. After the war between Charles I and Parliament wild deer could be found in only five localities. During the protectorate the raising of foxhounds or harehounds became common throughout the country; the land was overrun with foxes, which killed many lambs, and there were communal as well as private fox hunts. The organization of fox hunting clubs dates from the time of Charles II, when the Charlton Hunt was established; about a hundred years later subscription packs were formed. Riding with the hounds attained its present popularity in England in the nineteenth century. The extent of the practise is indicated by an estimate made about 1900, which found the number of hunting horses in Great Britain to be 200,000 with 67,000 men attending them. Fox hunting has developed only in countries with a large British population and among people of British heritage. Of the eighty-six packs of foxhounds used outside the British Isles in 1925 there were forty-seven in the United States, sixteen in New Zealand, ten in India, four in Australia, four in east and South Africa, three in Canada, one in China and one in Palestine. Wherever it has developed, hunting with horse and hounds has been limited to the aristocracy and the leisure, sporting and military classes. Until recently it was restricted to the landed gentry; in Great Britain it is still a matter of considerable social prestige.

In the New World game was abundant at the time of settlement; and hunting, which until recently occupied a prominent place in the life of the people, was the theme of the popular novels of James Fenimore Cooper. The move-

ment into the plains country found a new source of game in the wild buffalo, but within a few decades it had been exterminated. Hunting is still of minor economic value in many sections of the south but has practically disappeared in most other parts of the United States except as a sport. Big game hunting in Africa was first brought to popular attention by the exploits of Du Chaillu and of P. T. Barnum; later Theodore Roosevelt's accounts of African wild game were read by millions. Roosevelt's example has been followed by many Americans and Europeans, whose exploits have been much heralded by cultivated publicity in the press.

HUNTINGTON, COLLIS POTTER (1821-1900), American captain of industry. Huntington was born in Connecticut of a poor family, and

his formal education ended when he was fourteen years old. After peddling watches through the south he ran a general store in Oneonta, New York. In 1848 Huntington set out for California. During a detention of three months on the Isthmus of Panama he increased his fortune from \$1200 to \$4000 by shrewd trading. When he arrived in Sacramento he set up a hardware store, which later became one of the largest in the city and of which Mark Hopkins soon became a partner. Huntington and Hopkins, with Leland Stanford and Charles Crocker, who ran a general store in the same town, were persuaded by T. D. Judah, an engineer, to construct a railroad across the Sierra Nevadas. They began with less than \$1,000,000, a land grant and subsidy from Congress; the final cost of the road proved to be \$50,000,000. In 1861 they formed the Central Pacific Railroad Company, of which Huntington was vice president. Their success was largely due to Huntington's tireless energy and great business acumen and to his frequently unscrupulous methods, especially in the building of the Southern Pacific Railroad, with which his name is most closely identified. Of the two entrances to southern California over the gorge of the Colorado River one at Yuma was located on an Indian reservation; Huntington built across this and then asked permission from Congress. Lobbying of a questionable character was commonly practised and contracts were let to construction companies in which Huntington and his friends held control on terms costly to minority stockholders. The Southern Pacific controlled California for a quarter of a century, politically and commercially. After Huntington's death his holdings worth about \$50,000,000 were sold in the east and the railroad monopoly was broken.

Huntington was a man of Herculean strength and stature with a keen mind and few interests outside his work. He was persistent, courageous and imaginative but at the same time calculating, domineering and often vindictive. He was not interested in movements for social welfare and when he died left little of his fortune for public purposes.

HUSAYN A'LI, MĪRZĀ (Bahā' Allah) (1817-92), Persian religious reformer. Mīrzā Husayn, known as Bahā' Allah, the Splendor of God, was converted to Babism at about the age of thirty and after the death of the Bāb in 1850 became the outstanding leader of the sect. Exiled from Persia, he was allowed to settle in Turkey. He passed the last years of his life, surrounded by a group of disciples, at Saint Jean d'Acre in Syria. The leading ideas of Bahā' may be found in his sayings and writings, the most important of which are *Kitāb-al-Ikān* (tr. by Ali Kuli Khan and H. MacNutt as *The Book of Assurance*, New York 1924) and *Kitāb-al-Akdas* (Bombay).

Bahā' gradually discarded the concepts of the Bāb and finally asserted that he himself was the divine manifestation whom the Bāb had predicted; his religion dropped the name of Babism and was called Bahaism. While the doctrines of the Bāb had remained very oriental, very Persian and very national and while Bahaism is a link in the chain of all the Persian sects, Bahā' turned, on the contrary, in the direction of the European world and modern thought and claimed to express the form of religious sentiment most suited to the entire contemporary world.

Bahaism with its emphasis upon the oneness of all religions is an interesting attempt to promote an increased spirit of unity among mankind and to revive the mystical element in a world preoccupied with material progress. Its central thought is the union of all humanity by means of broader religious concepts and a spirit of mutual aid and brotherly love. To achieve this prejudices, such as those of race, tribe and nationality, must be discarded. There is no dogma in Bahaism except perhaps an acceptance of the idea of a divine spirit rather than of a definite personal god and a belief in progressive revelation. Bahā' asserted that every religion had been suited to its period and had been based upon divine revelation; the revelation of the new era was that of Bahā' and accordingly members of all other religions were exhorted to follow it. Bahā' condemned wars and suggested a central council at once religious and political to settle all differences between states. A single universal language, perhaps Esperanto, was to be adopted. Social distinctions were to be preserved but the rich were urged to share their possessions. The study of sciences and arts conducive to the improvement of the conditions of life were encouraged. In each village a council was to be established, supported by voluntary contributions, fines, a capital levy and the inheritance of prop-

erty in the absence of other heirs; an important share of the revenue was to be devoted to education and hygiene.

After the death of Bahā' his son, 'Abd-al-Bahā', succeeded him. 'Abd-al-Bahā' not only contributed to the philosophy of the movement but by his zealous propaganda gained it a number of converts in Europe and the United States.

HUSKISSON, WILLIAM (1770-1830), British statesman. Huskisson was introduced to public life by Pitt. He later became associated with the Canning reform group of the Tory party and on all general economic questions was one of the most informed parliamentarians of his day. He was an influential member of the Bullion Committee of 1810, whose famous report expounding the Ricardian theory of the inflation of the British currency he defended in a widely circulated pamphlet. In the many discussions on currency during the subsequent years Huskisson did much to popularize the monetary doctrines of the economists and in general he endeavored, with such moderation and opportunism as might be expected from a practical statesman, to translate the theories of the classical economists into state policies. He exerted a great influence on corn law legislation during the period from 1815 to 1828, defending at first the act of 1815 but after 1821 becoming more and more in favor of freer trade in corn. As president of the Board of Trade from 1823 to 1827 in the ministries of Liverpool and Canning, he was at once the custodian of the growing commercial and manufacturing interests of northern England and the enlightened reformer acting in accordance with the canons of the new economics. His reform of the navigation laws, which opened the commerce of the colonies to all European or other states prepared to reciprocate and allowed the ships of the reciprocating countries to share the carriage of goods, was the most substantial breach in the navigation laws previous to 1849 and helped to enrich the empire by enlarging its trade relations with other countries. At the same time he laid increased emphasis on imperial preferences in the duties imposed within the colonies under British acts and in Great Britain on certain goods

imported from the colonies. In order to extend British trade, abolish the vast social evil of smuggling and improve the processes of British manufacturers by exposing them to the fresh winds of competition he effected the first comprehensive tariff revision of the century, involving the removal of prohibitions and prohibitive duties and the establishment of the general principle that 30 percent should be the upper limit of protection for manufactured commodities. He encouraged steam transportation, both railroad and steamship, and sponsored the amendment of the combination laws, which allowed a greater degree of freedom to workers.

HUSS, JOHN (Jan Hus or Huss) (c. 1370–1415), Bohemian religious reformer. Huss was born at Husinec in southern Bohemia of a poor Czech family and studied at the University of Prague. In 1396 he became master of arts, in 1400 priest, in 1401 dean of the philosophy faculty and in 1402 rector of the university. He became absorbed in study of the writings of the English reformer Wycliffe, using them first as a source of philosophical and theological erudition and then, although he rejected the arguments on transubstantiation as well as many of Wycliffe's other strictures against Catholicism, embracing their basic ideas on ecclesiastical reform. He adapted to conditions in Bohemia the Wycliffite program with its nationalistic, anti-papal coloration and its proposal for the erection of a "poor church" in harmony with the ideals of primitive Christianity. The campaign which he conducted as university teacher and priest at the Bethlehem Chapel after 1402 welded the Czechs, who at that time were in the midst of an intellectual efflorescence, into a common reform movement based partly on a long prepared protest against the corruption and worldliness of the church; partly on a nationalistic hostility to the Germans, who constituted a large part of the ecclesiastical hierarchy as well as the dominant element in the Bohemian bourgeoisie. The first serious conflict between the Hussites and the allied Germans and clergy centered in the university and was precipitated by the summoning of the Council of Pisa in 1409 to deal with the papal schism. When the German professors disobeyed King Wenzel's order that they maintain

neutrality and so permit him to cooperate with the council, the king yielded to Huss' imprecations to destroy the German hegemony at the university. By the decree of January, 1409, a new university constitution was established, which allotted three votes to the Czechs and only one to the other three foreign nations combined, whereas hitherto each nation had held a single vote. The result was the immediate withdrawal of the Germans, their founding of the University of Leipsic and the transformation of the University of Prague from a cosmopolitan cultural center into a national university.

At the end of 1409 the Bohemian archbishop Zbynek received plenipotentiary power from Pope Alexander V to proceed against Wycliffite doctrines and books. In 1410 he defied the excited nation and excommunicated Huss. Two years later when Huss joined the controversy over indulgences, the theological faculty, unable to follow him in his attack upon the papacy and an established Catholic tradition, abandoned him. The dissension heightened by the martyrdom of three lay Hussites and by Huss' demand that the theological faculty present Scriptural refutation of his position on indulgences induced Wenzel, who had hitherto refrained from interference, to request Huss' retirement from Prague. Huss complied, and in the town of Kozl Hradek composed his tract *De ecclesia* (1413).

As public preacher and agitator Huss envisaged no more than national ecclesiastical reform; his Wycliffism was conditioned by Czech nationalism. The *De ecclesia* marks the beginning of his fervent espousal of the broader Wycliffite doctrine concerning the true church of Christ. Based on Wycliffe's treatise of the same title, the *De ecclesia* contended that the true church is not the narrow Catholic institution but the entire community of those who since the beginning of time have been predestined for salvation. The elect owe fidelity only to Christ and need not follow an erring pope. Huss had already appealed to this doctrine against the papalistic Roman council which condemned the writings and followers of Wycliffe in 1413, when Emperor Sigismund, who as prospective heir to the Bohemian throne was eager to settle the Hussite controversy, invited Huss to meet the chief dignitaries of Christendom at the oecumenical Council of Constance, summoned by the emperor to assemble in November, 1414. Huss accepted with confidence, but after his arrival at Constance he was imprisoned by the clergy. Although he had

guaranteed Huss' safe conduct Sigismund soon perceived that he must sacrifice him for the sake of church unity. After first condemning Wycliffe and his doctrines the clergy examined Huss in June, 1415. With a heroic submission to the fate of martyrdom he remained steadfast against the council's importunate efforts to secure his general recantation, clinging to the position that he could admit the error of his doctrines only on the authority of Scripture. On June 24 his books were ordered burnt and on July 6 he was condemned, subjected to ceremonial degradation as a heretic and sent to the stake. The following year the Bohemian nobleman and Hussite Jerome of Prague suffered the same fate. The non-Catholic but Christian doctrine of the true church of Christ—the chief ground on which the council had condemned Huss—was upheld more than a century later by Luther, who declared that Constance had erred in a crucial opportunity to destroy the system of papalism and legal Catholicism in general.

The martyrdom of Huss and Jerome aroused a fierce outburst of nationalism in Bohemia and in 1419 war broke out between the Hussites and the imperial armies aided by papal crusaders. The Hussites (*see* SECTS) divided into two parties. The Utraquists, who found in the lay chalice a symbol for a program which was essentially a continuation of Huss' demand for a national reformed church, represented the conservative party and were recruited chiefly from the nobles and the upper Czech bourgeoisie. The Taborites, or radicals, developed and to a certain extent distorted the social aspects of Wycliffism; they became the party of the Hussite peasants and urban working men, preaching a religious renovation to simplify the cult and a social revolution in the name of Christian equality. The Taborites never recovered from their overwhelming defeat in 1434. But the Utraquists after having received the grant of the lay chalice by the Prague Compacts of 1433 and the Diet of Iglau in 1436 survived as the constituents of the Bohemian reformed church under a series of intermittently abrogated and superseded compromises, until in the sixteenth century the more conservative of them became virtually indistinguishable from the Catholics and the more radical became identified with the Lutherans or other reformed sects. In the latter half of the fifteenth century a modification of the tenets of the advanced party of the Hussites was developed by the Bohemian Brethren (also Moravian Brethren), who evolved the idea of an asso-

ciation of laymen isolated from society and basing their lives on the ethical precepts of the gospel. Although included in the privileges of the *Bohemica confessio* of 1575 the Bohemian Brethren, along with all the other remnants of Hussites, were crushed or finally expelled from Bohemia by the Catholic Austrians in 1620.

HUTCHESON, FRANCIS (1694–1746), Scottish philosopher and economist. Hutcheson, the son of a Presbyterian minister, was born in Ireland. He studied at the University of Glasgow, conducted a private college in Dublin and in 1730 became professor of moral philosophy at Glasgow.

Beginning as a follower of Shaftesbury, Hutcheson contributed much to the introduction of humanism into the Scottish universities. The central point in his writings and his chief contribution to philosophy was his effort to work out the doctrine of a moral sense, an immediate, indefinable perception approving of actions which procure what he was the first to call "the greatest happiness of the greatest numbers." The first three editions of his work on aesthetics contain mathematical formulae for expressing ethical relations, which caused Sterne to describe Hutcheson as the man "who plus's and minus's you to heaven or hell, by algebraic equations." Hutcheson extended to the field of economics the concept of a natural order working through physical forces and human psychology. There is considerable economic material in his works, particularly in the *System*. Adam Smith, who was a student in his class in moral philosophy in 1740 and later called him "the never to be forgotten Hutcheson," learned from him to esteem "natural liberty." Smith was influenced by the *System*

in his treatment of the division of labor, labor as a standard of value, value in use and value in exchange, the origin of capital, money and the maxims of taxation. Hutcheson also had considerable influence on Hume and through these two on the development of English classical economics.

W. R. SCOTT

HUXLEY, THOMAS HENRY (1825-95), English biologist and protagonist of the theory of evolution. After attending Charing Cross Hospital as a medical student Huxley turned to biological research. His voyage of scientific exploration to Australia and the East Indies laid the foundation for his wide knowledge of organisms. He produced some 170 scientific monographs, several of which became classics.

Huxley's fame rests primarily, however, on the part he played as an advocate of the theory of evolution. Darwin was not a controversialist; in order to weather successfully the storm aroused by his *Origin of Species* he needed the bold and eloquent support given by Huxley in England and Haeckel in Germany. By knowledge and temperament Huxley was ideally fitted for this role. He was an ardent defender of the scientific spirit against the obscurantism of orthodox belief. His famous retort to Bishop Wilberforce, his controversies with Gladstone, Canon Liddon and the duke of Argyll bring evidence of his forensic skill. Some of his lectures were convincing polemics which served to popularize evolution.

Huxley was at no time a blind follower of Darwin nor did he accept unreservedly the principle of natural selection. An opponent not of religion but of dogmatic theology, he character-

ized himself as an agnostic determined to follow reason in all matters of the intellect. Sensitive to the arts, a student of literature, scientist, philosopher, educator and organizer, he was one of the richest personalities of his day.

HYDE, EDWARD, LORD CLARENDON.

See CLARENDON, FIRST EARL OF.

HYNDMAN, HENRY MAYERS (1842-1921), English writer and social democratic pioneer. Hyndman was born in London of a wealthy family, studied at Cambridge, read for the bar, spent a few years in sport and travel and then became a war correspondent with Garibaldi's forces for the *Pall Mall Gazette*. Neither a patient scholar nor a cautious investigator but a politician and journalist gifted with quick apprehension, a forceful style and considerable oratorical power, his career from about 1864 until 1880 was that of the typical well to do English radical of the mid-Victorian era. He sympathized with the Italians struggling to be free, disliked Prussia and hoped for a French victory in 1870, stood up in defense of the Paris Commune and supported Indian and Irish protests against British domination. During the trade depression which set in about 1875 and deepened through the late eighties a rebellious spirit against the self-complacency of mid-Victorian liberalism gradually grew in Hyndman, and in this mood he read in 1880 the French translation of the first volume of Marx' *Capital*. From a disgruntled radical without a clear program Hyndman became a fierce anticapitalist and socialist. He called upon the aged author of *Capital* and his impression was overwhelming, although Marx never came to trust him fully. In 1881 he organized the Democratic Federation (after 1884 the Social Democratic Federation). Although some of the ablest Englishmen of the time labored

indefatigably for it for over forty years, Hyndman's hope of creating a mass party was not realized; the membership was never much more than 10,000. Hyndman ran for Parliament several times but never succeeded in getting elected. He scorned trade unions, utterly misunderstanding the revolutionary mission that Marx ascribed to them. While the federation was never more than a propagandist organization enjoying little contact with the working masses it did keep alive a sense of the value of action as a socialist technique. It later became the Social Democratic and finally the British Socialist party, the latter, without Hyndman, merging at last into the Communist party. His Marxian economics did not go beyond the labor theory of value, surplus value, robbing the workers, speeding the social revolution. He failed to see the need for the second and third volumes of *Capital*, which were supposed to solve the problem of how equal capitals with unequal labor power units and consequently unequal surplus values could produce equal average rates of profit; he failed to take account of the neutralizing factors which according to Marx retard and mitigate crises that might otherwise lead to the collapse of the capitalist system. Hyndman took from Marx only what might be effective for social revolutionary agitation. Even where he appeared to differ from Marx, namely in the economic or materialist conception of history, he really touched not Marx but his crude interpreters. To the last of his days he dogmatically adhered to Lewis H. Morgan's exposition of primitive society, never suspecting that a new critical school had challenged older theories of primitive agrarian communism.

Hyndman was not, in fact, the successor of Marx but was of the line of such social reformers and Tory democrats as Fielden, Sadler, Oastler, Disraeli and such Chartists as J. R. Stephens. He was close enough to Tory ways and interests to get Tory financial support for anti-Liberal parliamentary contests. The few conceptions he took from Marx were to him but sticks with which to beat the bourgeoisie. He was a staunch patriot and self-conscious patrician, burning with zeal to see England great, generous, mighty, and all his countrymen well fed, well housed and warlike. He detested all foreign powers that might threaten the greatness of the British Empire. He left the British Socialist party in 1914 when it opposed the war. He hated the Bolsheviks as pro-Germans and destroyers of the parliamentary and democratic

institutions constituting the legacy of a thousand years of great Englishmen.

MAX BEER

Boston 1921); *Clemenceau, the Man and His Time* (London 1919); *The Evolution of Revolution* (London 1920); *The Awakening of Asia* (London 1919); *The Record of an Adventurous Life* (London 1911); *Further Reminiscences* (London 1912).

Consult: Hyndman, R. T., *The Last Years of H. M. Hyndman* (London 1923); Gould, F. J., *Hyndman, Prophet of Socialism (1842-1921)* (London 1928); Beer, Max, *A History of British Socialism*, 2 vols. (London 1919-20); Rothstein, T., *From Chartism to Labourism* (London 1929); Clayton, Joseph, *The Rise and Decline of Socialism in Great Britain 1884-1924* (London 1925).

IBN-HANBAL, AHMAD IBN-MUHAMMAD (780-855), Mohammedan theologian and jurist. After studying theology and jurisprudence in his native city, Bagdad, and after extended travels in Mesopotamia, Syria and Arabia he finally became a student of al-Shāfi 'i.

Ibn-Hanbal is the fundamental authority of the Hanbalite school, the latest of the four Islamic schools of law (*madhāhib*) recognized by the orthodox Sunnites. Declaring himself the representative of an extreme Koranic orthodoxy ibn-Hanbal rejected all concessions to rationalistic interpretation. As such he was the object of ruthless persecution during the period when the liberal theology of the Mutazilites enjoyed governmental recognition; after the victory of orthodox doctrine under the caliph al-Mutawakkil, however, he gained great prestige. In keeping with his dogmatic position ibn-Hanbal recognized as the foundations of law only the Koran and the *ḥadīth*, the tradition concerning the acts and utterances of the Prophet, opposing even recourse to analogy on the basis of these sources, let alone purely rational legal concepts. A juristic system in the true sense of the term was scarcely to be constructed on such principles, and for this reason the followers of the three other schools opposed the recognition of these fanatical theologians and untiring collectors of traditions as true legal scholars. Ibn-Hanbal's collection of traditions, the *Musnad*, comprising between 28,000 and 29,000 items, was first edited after his death by his son 'Abdallah, who made still further additions to it. Merely an enormous accumulation of material with no systematic formal force, the work remains free of any bias but is also entirely lacking in critical content.

Any collection, nevertheless, no matter how replaceable, was necessarily acceptable if all legal relations were to be regulated on purely traditionalistic lines.

In keeping with his strict adherence to the traditionalistic legal doctrine ibn-Hanbal bequeathed to his followers, the Hanbalites, greater rigorousness in all rituals and social relations and a fanatical intolerance. Current up until the sixteenth century in Mesopotamia, Syria and Palestine, their doctrine won temporary support even as far as Persia. It experienced a notable revival with Taqīy al-Dīn ibn-Taymīya (1263-1328), to whose ideas the reactionary reform movement of the Wahhabites in the eighteenth century was related. Of essential significance today only in the interior of Arabia, the Hanbalistic doctrine is by far the least accepted in the course of studies at the Azhar Mosque in Cairo, the leading center of Mohammedan theological studies.

IBN-KHALDŪN (Waliy al-Dīn Abū-Zayd 'Abd al-Rahmān Ibn-Muhammad) (1332-1406), Mohammedan historian and philosopher. From the autobiography appended to his history it appears that ibn-Khaldūn was born in Tunis and received a liberal education, displaying an unusual aptitude and inclination for study. He served in various capacities several of the potentates who divided Moslem north Africa and Spain between them; among other posts he held that of envoy to the court of Peter the Cruel at Seville and for a time he lived among the nomad Arabs. On his way to Mecca in 1382 he passed through Cairo, where he remained and was appointed professor of law and later Malikite judge, an office which he occupied intermittently until his death.

Ibn-Khaldūn's extant literary work consists of a history in three parts, which in its printed form fills seven volumes (Bulak 1867). The nar-

rative portions (parts two and three) begin with a sketch of universal history prior to Islam and contain histories of the Islamic dynasties down to his time. Of these the most important is the history of the Berbers (French translation by W. M. de Slane, *Histoire des berbères et des dynasties musulmanes de l'Afrique septentrionale*, 4 vols., Algiers 1852-56; new ed. by P. Casanova, 2 vols., 1925-27), which is the basic source for modern knowledge of Moslem north Africa. These sections, which deal almost entirely with political history, remain a dry narration of events. Nevertheless, they are significant both because of their critical attitude toward historical material and because of the abandonment of the traditional chronological approach in favor of the method of treating history by nations and dynasties which was introduced by al-Mas'ūdi.

But even more attention has been attracted by the volume of prolegomena (French translation by W. M. de Slane, in *Notices et extraits des manuscrits du roi*, vols. xix-xxi, 1862-68) which opens the work. It is primarily a philosophy of history but touches on sociology and economics and toward the end becomes encyclopaedic in conformity with ibn-Khaldūn's doctrine that history is the study of all social phenomena. The author is justified in regarding his work as starting an original line of inquiry in Arabic literature, in which until quite recent times he found no successors. It is unique in that, unlike the purely annalistic histories of the Arabs, it formulates generalizations based on the study of the records which form the subjects of the subsequent volumes. Having made observations upon the effect of climate, altitude and other physical factors on conduct and character, and having restricted his subject to the temperate zones, he emphasizes the distinction between nomads and town dwellers. The former roam about the desert in groups held together by 'aṣābiya (clannishness), a sentiment originating in blood relationship, which causes each member to subordinate his individual interests to those of the clan. The wants of persons in this state are exiguous, and they display many virtues, of which courage is the most conspicuous, although they have no scruple about raiding and pillaging. The need for justice within the group causes leaders to arise, and when the groups become sufficiently numerous they migrate to fertile lands and ultimately change into town dwellers or subdue already existing town communities, adopting the previously established civilization. The town

dweller become luxurious and lose their capacity for self-defense. The rulers, as their wants increase, must resort to constantly increasing taxation; and resenting the claims of their clansmen to equality with themselves they rely for aid on foreign supporters, who become necessary moreover because of the decline of the clansmen as warriors. Thus the state grows decrepit and becomes the prey of a fresh group of nomads, who undergo the same experience. The period which constitutes the normal life of a state is 120 years, or three generations of forty years each.

Ibn-Khaldūn's deductions are made from the history of the Islamic dynasties, chiefly those of north Africa and Spain. It does not occur to him to suggest remedies which might arrest the decay of the state. The latter he supposes to have by nature a fixed duration, with periods of growth, maturity and decay, analogous to that of the individual; and he is unaware of any form of government save an Oriental despotism.

Of his views in economics the most noteworthy is the observation that price is determined by the cost of production, into which taxation enters. He also appears aware of the influence of supply and demand on price. He analyzes the dangers which arise when a government takes part in trade and argues that increase of population brings increase of wealth through division of labor while increase of wealth causes an increase of population.

Despite the new point of view introduced by Ibn-Khaldūn and despite the continuous use of his work in the East he had no followers of any importance. In the West little was known of his work until the nineteenth century.

IBN-MISKAWAYHI. See MISKAWAYHI.

IBN-TAYMĪYA, ABU-AL-'ABBĀS AHMAD IBN-'ABD AL-ḤALĪM (1263-1328), Mohammedan jurist and theologian. Ibn-Taymīya was born in Harrān and spent most of his life in Damascus with occasional visits to Egypt. His biographers state that he studied under the ablest teachers the various subjects cultivated by the Moslems and was an omnivorous reader.

His significance as a theologian lies in his revival of Hanbalite doctrine, in his transmission of it to modern times and in the acceptance of his views by the Wahhabis, who ascribe to Ibn-Taymīya a role similar to that of Luther in western Christendom.

He was one of the most voluminous of Arabic authors and is said to have composed five hundred volumes, the titles of which have been preserved. Several have been printed, notably the collection of Ibn-Taymīya's "opinions," which occupies five bulky quartos (*Fatāwā*, Cairo 1908-11); his refutation of the Shī'a in four volumes (*Minhāj al-Sunnah' al-Nabawiyyah*, Cairo 1904); and his treatise against Christianity (*Al-jawāb al-sahih liman badal dīn al-Masih*, 4 vols., Cairo 1905). Ibn-Taymīya used the matter of the last named book in another of his works, and he may have followed this practise in his other writings. His political treatise is *Al-Siyāsa al-Shar'iya fī Al-Rā'i wal-Rā'iya* (Legal administration dealing with the shepherd and flock, Bombay 1888). The work consists of maxims for the guidance of rulers and their subjects, often homely in character and illustrated by anecdotes and sayings ascribed to Greek, Persian and Islamic sages. Probably the most noteworthy passages are those in which the author proves that humanity is steadily progressing and in which he advises rulers to divert attention from political controversies by circulating fictitious alarms.

B., *Development of Muslim Theology, Jurisprudence and Constitutional Theory*, Semitic series, vol. ix (New York 1903) p. 270-78, 283-85; Goldziher, Ignaz, *Die Zāhīriten, ihr Lehrsystem und ihre Geschichte* (Leipsic 1884) p. 188-93.

IBSEN, HENRIK (1828-1906), Norwegian dramatist. He won his world fame as author of a series of so-called social dramas, starting with *The Pillars of Society* (1877) and *A Doll's House* (1879) and ending with *Rosmersholm* (1886). The

theme of all these plays is the struggle of individuality against society, a theme going back to the very beginnings of Ibsen's literary activity, when as a young man he wrote the tragedy *Catilina* (1850). His first modern drama, *The Comedy of Love* (1862), was a bitter satire on the social conventions ruling the relations between man and woman and fettering the souls of both. Then came after the Dano-German war of 1864, when he had expected his own nation to step forward in defense of the Danish brethren, his outburst of rage against his countrymen, erecting in *Brand* (1866) the tragic figure of the uncompromising champion of moral demands and picturing in *Peer Gynt* (1867) the versatile illusionist who always shirks the truth and the honest deed. These two dramas may be called the most strongly personal of his works, highly emotional and abundant in poetic expression. In a realistic comedy, *The League of Youth* (1869), he showed the character of Peer Gynt transformed into a modern politician; and then from the seventies he turned to society as a whole, confronting it with the personal demands of truth and self-realization.

In many cases Ibsen's point of departure was the actual questions or conflicts of his day, like the struggle recently begun for the emancipation of women, or conflict between modern science and Biblical Christianity or even more explicitly such current topics as Samuel Plimsoll's agitation against the "swimming coffins" sent out by unscrupulous shipowners (*The Pillars of Society*). His general ideas, however, were deeply rooted in the spirit of the age. Ibsen was the most consistent representative of the individualism of the nineteenth century, and he pushed the demands of personal liberty to their extreme consequences. But in thus venting the ideas of his age he made them revolutionary forces, questioning the foundations of society. It is characteristic that he repeatedly scoffed at the word duty, concentrating in it all kinds of conventional demands upon personal behavior. He recognized no duty but the fidelity of every man to the commands of his own conscience, his character and his faculties. This was the meaning of his slogan for social life: "Truth and liberty." Of all his characters the man who was nearest to his conception of a social ideal was the hero of *An Enemy of the People* (1882), the rebel against social tyranny.

To Ibsen the moral problem involved in the conflict between individual and society was at the same time a psychological problem, and in the

succession of his dramas can be seen the steady growth of psychological interest and intimate character studies. Ever more the conflict is one between inner forces in the man himself, his fight against the inherited or accepted moral traditions which dominate his own mind. Such is the theme of *Ghosts* (1881) and *Rosmersholm*, and in the dramas which followed the problem is confined to the fight for complete self-realization as opposed to the merely artistic view of life. The combination of moral and psychological conflict was the element that gave power to his dramas, and by translations into many languages and still more by theatrical representations all over the world they became a great force in the education of humanity for liberty.

ICONOCLASM, the hostility to images, is a recurrent phenomenon. The term has been used specifically to designate a movement against the worship of images in the Byzantine Empire in the eighth and ninth centuries A.D. but is also used in a more general sense to characterize comparable manifestations. The earliest known appearance of iconoclasm is the heresy of Ikhnaton, king of Egypt (c. 1375 B.C.), which substituted for a multiplicity of gods in human or animal form "the splendor which is in the disc of the sun." A strong iconoclastic spirit voiced by the Hebrew prophets expunged from the Bible records of the old idolatry; only a few cases, such as the story of Moses' brazen serpent, remained. The prophets in their attacks assumed that the image, not the being for which the image stands, was worshiped; and they had no difficulty there-

fore in reducing such worship to absurdity (*Isaiah* XLIV: 9-20; *Jeremiah* x: 3-5; *Psalms* CXV: 4-7). The apocryphal *Epistle of Jeremy* is a tirade on the worthlessness of images, which is the theme of iconoclasts of all ages; the early Christians, for example Lactantius, condemned pagan idolatry as being utterly foolish. As the church absorbed proselytes in large numbers it made concessions. It drew a distinction between images and idols, attacking the latter as fanciful representations of phantoms or demons and approving the former as genuine forms of Christ, His mother and His saints, meriting worship because of the miracles they had wrought. The iconoclastic principle was surrendered; it was not the worship of images that was condemned but only that of "false" images. The Roman church became iconoclastic toward other religions only and has remained so. The Spanish conquerors showed zeal against heathen idols because they were devoted to Christian images.

In the Eastern church, where the worship of images proceeded to excesses as great as those of paganism, a movement against the practises was led by the emperor Leo III (716-40) and was continued with great fervor by his son Constantine Copronymos. The worship of images was declared to be idolatry, images were broken up and their defenders persecuted. The champions of images eventually prevailed but their councils expressly declared that images were to be venerated, not worshiped.

In the west organized attacks against images, which did not begin until Wycliffe and Huss, culminated with the Reformation. Protestants complained that the Roman Catholics taught that there was a virtue in images comparable to that which magicians claimed for the figures of constellations. The Calvinists were especially violent; in the Low Countries and France they sacked churches and destroyed images. In England iconoclasm found no opportunity for expression except during the military operations of the Great Rebellion, when a great many statues and much stained glass were smashed. In Protestant countries the cult of images has never recovered, and wherever they have gone Protestant missionaries have served as agents of iconoclasm. In Roman Catholic and Orthodox countries the veneration of images flourishes and tends to relapse into adoration. In Arabia opposition to idolatry culminated with Mohammed, who prevented the recurrence of images by prohibiting all representations of human or animal forms. In Islamic Persia and India, however, human

miniatures of considerable artistic merit were fashioned in defiance of Mohammed's precept.

The claim of iconoclasts that they are striving to bring back religion to its original purity is justified in so far as idolatry is not addressed to the images or fetishes but to the powers attached to them; the worship of the object itself is a corruption. It is doubtful, however, whether ritual ever existed apart from material vehicles of the powers to whom the worship was addressed. Iconoclasm attacks primarily human representations because they are more likely to usurp the place of the deity they represent; non-human shapes keep their representational character. Mohammed, uncompromising as regards idols, retained the black stone of the Caaba. When the Church of England removed images it retained symbols, such as the triangle for the Trinity.

Iconoclasm tends to be concomitant with simplification and centralization both in religion and in government. Ikhnaton came at the end of a period of imperial expansion and expressed autocratic tendencies. The Hebrew prophets worked to concentrate the worship of one god in one temple. It is not a coincidence that the first Roman emperor to embrace Christianity and to condemn pagan images tried to arrest the decentralization begun by Diocletian; after him the process resumed as did the adoration of images. The iconoclastic emperor Leo III was a centralizer and his son asserted imperial supremacy in ecclesiastical affairs. The Reformation marks the end of the feudal period and the beginning of absolutism. Mohammed after abolishing idolatry proceeded to unite Arabia and then to impose religious and political unity on other nations.

Iconoclasm is essentially a product of urban life. Christianity first developed in the cities; as it absorbed the rural population it lost its iconoclastic principles. The iconoclastic French Revolution was the result of a steady movement toward the concentration of all power in Paris. The recent Spanish and Russian revolutions, which surged with iconoclasm, were the work of city populations. In the latter instances iconoclasm is an overt expression of the protest of the masses against the churches' participation in their exploitation. Secularistic and rationalistic attitudes concomitant with the spread of popular science and the liquidation of illiteracy provide fertile backgrounds for iconoclastic movements.

IDEALISM. In the popular sense the term idealism means a tendency to oppose the representations of the mind (ideas and ideals) to empirical reality and to give them a predominant position and role in the scale of human values. Since by their very nature ideas and ideals are as far as possible independent of the limitations and imperfections of empirical reality and have at least aspirations toward the perfect and the absolute, it follows that idealism in the popular mind leads men to live in a superworld remote from what is usually regarded as common reality and to be indifferent to and disdainful of the things of this lower world. Even in the philosophic sense idealism is credited with the same tendency to grant to spiritual representations primacy over nature and experience. There is in the philosophic use of the term, however, the methodical effort to explain these objects in terms of ideas and then to reintegrate the unity of the world and of experience. This methodical and critical labor of philosophy has had various phases during which the conception of idealism has become radically transformed.

Although the word idealism as designating a philosophic tendency and school has been used only in modern times, the beginning of idealistic speculation is to be found in Plato. The fundamental attitude usually considered idealistic is peculiar to the Platonic philosophy and consists in attributing autonomous reality to Ideas and in combining them into an "ideal world," as opposed to the world of empirical flux. All the characteristics of ancient and mediaeval idealism are present in Platonism. Ideas are not the prod-

ucts of human ideation and are therefore not subject to the mutability and errors of the thinking subjects but are perfect entities anterior to men and all things of experience, unchanging types and patterns after which things subject to birth and death are modeled. The very thoughts of man are but imitations of the eternal Ideas, which may therefore be considered the thoughts of God that preside at the creation of the world (*Timaeus*). Platonic idealism is thus objectivistic and transcendental. Although Plato had given the world of flux an ideal foundation and thus attempted to explain the recurrence of stable notes in the incessant change of empirical things—such as order in the movements of the stars or the preservation of organic types—nevertheless, as he set off the two worlds too sharply against each other he did not succeed in reaching a satisfactory solution. On the contrary, it is evident that he became the inspirer of dualistic theological speculation, which opposes heaven to earth, the creator to the creature, and regards the world of phenomena as a pilgrimage toward a stable and eternal goal. Christian patristics and scholastics are both saturated with Platonic idealism.

If in ancient idealism ideal reality was thought of as transcendent and therefore the attitude of human thought toward it was purely contemplative, in modern idealism, on the contrary, there is evident a tendency to regard ideas as acts and products of the intellect and the objective and natural world as the conscious content of this renewed spiritual subjectivity. Not only do the ideas descend from the Platonic superworld to empirical reality, but the reality, thus vivified and idealized, gravitates around the center of the human intellect. This double process of assimilation has gradually realized itself by steps often apparently opposed but in the last analysis converging. On the one hand, modern English empiricism has vindicated the claims of the human subject to the authorship of those ideas that formerly had seemed to come to him from above: the very term *idea*, which in Platonic philosophy was full of theological mysteries, has finally come to express purely empirical representation. Thus from an empirical source has sprung Berkeley's subjective idealism, which regards the objective world as a complex of representations in consciousness. On the other hand, with Descartes the rationalistic tendency centered the ideal world around the activity of the *cogito* and regarded this active thinking as the foundation of being. A more mature expression

of modern idealistic attitudes was given in the critical idealism of Kant. With Kant the epistemological significance of modern idealism becomes clear in contrast with the ontological and the theological character of ancient idealism: ideas are not transcendent and quasi-divine beings participating in some incomprehensible way in human thought and natural objects, but are acts and forms of the intellect, which models the empirical material received through the senses. The resultant of this synthesis of form and matter is what is called experience and comprises an element always mobile and variable, the sensible datum, and a stable and solid mental warp which lends order and law to the phenomenal world. Behind this experimental synthesis Kant nevertheless allows for the existence of a *Ding an sich*, a noumenon, as an unknowable substratum of phenomena. The effort of the post-Kantian idealism of Fichte, Schelling and Hegel has been applied to the elimination of this residue of transcendence and to the conversion of thought into the exclusive pillar of the universe. Moreover post-Kantian idealism set in greater relief, in opposition to Kant, the genetic character of mental activity and strove to demonstrate that the various ideal stages in mental organization correspond to the stages in the formation of the cosmos. In the realization of this task it has been guilty of manifestly arbitrary assumptions, making a misuse of a priori dialectic deduction and divorcing thought too absolutely from the human conditions of its presentation. The assumption, however, of a genetic point of view in the study of the problems of the mind marked the beginning of historicism and the evaluation of reality as a historical process of spiritual formation. This view, anticipated in the eighteenth century by the Italian philosopher G. B. Vico and emphasized by the romantics, in the beginning of the nineteenth marks a partial contrast with the Kantian ideal of a knowledge orientated toward the natural sciences and a more fundamental opposition to the transcendent idealism of ancient thought.

In the course of the nineteenth century idealism in the metaphysical formulation that it had received from German philosophy suffered a long period of eclipse. To this its dialectic abuses in part contributed, in part also the fact that the great progress of the natural sciences attracted the mind toward a naturalistic view of the world and of life and made the intuitions of the new historicism at least premature. For some decades

naturalism dominated the field of philosophical speculation, from positivism to the most radical forms of materialism. But toward the end of the nineteenth century there set in an idealistic revival, which became intensified during the twentieth. This began by assuming the character of a reaction against the natural sciences and against the tendency of the philosophy that had preceded to rely too exclusively upon the physical and biological sciences, contracting and repressing those spiritual values that cannot be weighed in a balance or observed with a microscope but which nevertheless are attested by consciousness. That this reaction was opportune and salutary is due to the fact that its promoters were the very students of the natural sciences (such as Poincaré and Mach) who gave particular emphasis to the conventionalized and hypothetical elements inherent in all naturalistic constructions and thus corrected the notion that science was an exact reproduction of a supposed objective reality. The philosophers who followed them undertook a saner and more modest task; namely, that of showing that those critics did not diminish the value of science, but rather increased it by affording an unexpected testimony to the originality and inventiveness of the mind of the scientist and transferred it to the proper sphere. Since the attacks of scientific thought—or rather of the naturalism that had arrogated to itself the right to represent such thought—have thus been met, those spiritual energies and values in contemporary idealistic philosophy that had formerly been stifled and repressed have been able to have freer course. A classification of the contemporary idealistic schools may be made by taking as a basis the several spiritual forms that each of the schools considers fundamental and primary. The rationalistic trends are represented by neo-Kantian schools, including the phenomenism of Renouvier, the Marburg school of Hermann Cohen and Natorp and the school of the philosophy of values of Windelband and Münsterberg, as well as by the post-Kantian and particularly Hegelian idealism of Stirling, Green, Caird, Bosanquet and Bradley in England, Royce in the United States, Spaventa and Gentile in Italy and Lachelier and Hamelin in France. The contingentist and intuitionist trends, which regard reality as something alogical and prelogical, that is grasped by an immediate intuition, are represented by Boutroux, Bergson and Le Roy. The psychological trends, which proceed from the data of the psychological consciousness and found on these a

spiritualistic metaphysics, are represented by the school of Ravaisson. The voluntaristic trends, which regard the will as an ideal and moral force, are best represented by Blondel's philosophy of action and by that which exalts practical activity into an intelligent principle for the reconstruction of experience, the idealistic pragmatism of Dewey. The historical trends, which in place of a unilateral priority of one spiritual form over another are partisans of an organic explanation and a harmonious constitution of spiritual forms having history as its center, find their most complete expression in Croce's philosophy of the spirit.

This rapid review of the principal historical attitudes of idealistic thought affords a means of understanding in their genesis and changes the social and political doctrines connected with the idealistic view of reality. Platonic idealism, with its conception of Ideas as universal and transcendent essences, has its complement in a political doctrine which makes the ideal state a transcendent and perfect existence above the changing scene of ephemeral and transitory individual interests. This doctrine has been the fountain of all the utopias in which humanity, groaning under the burden of oppression and injustice, has summed up its most profound social and ethical aspirations. The contrast between the perfect state and the existing state, which in Plato's *Republic* and in the utopias is merely implied, becomes explicit and emphatic in the conception of Christian Platonism. Thus St. Augustine opposes the City of God to the earthly city; and this antithesis dominates the whole mediaeval mentality. In general ancient idealism does not recognize individual values and rights in the presence of society and the state: the universal precedes the individual and is superior to it; the individual has his position and task preordained in the social organism and it is not in his power to modify them.

In contrast with the ancient, modern idealism places the center of the ideal world in the consciousness of the individual. Therefore also the politics of the new idealism removes the center of interest from the state as a theological and transcendent entity to human personality as an autonomous and infinite value. Modern idealism thus developed the concept of individual liberty in its varied forms—religious, civil, economic, political—and the concept of natural rights, inherent in the person and independent of all governmental recognition. In the presence of the individual thus emancipated the state assumes a

secondary and derivative existence as the product of a convention by which the individuals renounce a part of their liberty and of their original rights in view of the exigencies of their common life, but always within the limits of the utility and well being to be realized by means of that common life. From such a view, widely diffused during the course of the seventeenth and eighteenth centuries, there developed attitudes decidedly critical and polemical toward the existing states and social orders. Cartesian rationalism furnished the intellectual weapons for the waging of that stern struggle against the historical institutions which ended with the French Revolution. But the essential strength of the aggressive and polemical attitudes resided in the conviction that, as individuality and not the state was the fundamental value, there lay in the individual also the capacity to reform and renew. The individualistic ideal thus lent to action a tone of vital optimism.

The French Revolution, however, belied many hopes of its intellectualistic partisans. It showed that in idealism as embodied in historical institutions, in religion, in customs, in society, there was a force of resistance that revolutionary radicalism was not able to overcome. The political idealism of the nineteenth century, commencing with the period of the Restoration, has realized ever more completely that if the ultimate source of all spiritual values is in the individual, the latter in turn is here considered in his universality; that is, in those rational and moral aspects that link him to other individuals and whose external expression is historically conditioned. Idealistic historicism has thus reintegrated those values that the antihistorical mentality of the preceding century had wished to subvert. It has explained that the individual is not born free but becomes free with a constant endeavor to be free; that this liberty is not the negation of any social tie, but the conscious and virile acceptance of all the bonds that conscience itself represents to him as necessary for the realization of perfection and the common weal; that therefore human societies from the family to the state are not forces hostile and repressive to the personality, but means through which the personality forms and emancipates itself; that, in short, a purely revolutionary activity, with the illusory fancy of reviving elements and values purely individual by making a *tabula rasa* of all the labor of history, in reality tends to produce the opposite effect, to impoverish these individual elements and values and rob them of all content.

This work of reintegration was undertaken chiefly by German idealist philosophy. It has often, it is true, been obscured and distorted by the reactionary attitudes of the period of the Restoration in which it had developed. The Restoration, viewed today in the light of the whole course of nineteenth century events, was not merely expressed in legitimism or in the Holy Alliance but also included that slow and constant labor of assimilation and penetration whereby revolutionary radicalism and the forces and institutions of the past were fused together. But the Restoration in its beginnings conceived the anachronistic plan of annulling all the "innovations" of the revolution in spite of their world wide acceptance and reviving in its entirety a past that was beyond recall. This reactionary spirit influenced the German thinkers of the early nineteenth century, in particular Hegel, whose political doctrine appears to be a compromise between the liberal and individualistic tendencies of the Kantian philosophy and the reactionary absolutism of the Restoration. Thus Hegel on the one hand made liberty the center and pivot of political philosophy but on the other withdrew this liberty from the individual, its true source and seat, and transferred it step by step to the family, to the society, to the state. There was a profound motive of truth in that transference, in which family, society and state were conceived as means of expansion and perfection for the human personality; but Hegel was too easily prompted, by force of the very milieu in which he lived, to identify the concept of society with the semifeudal society of his time, and the state that was to embody liberty with the Prussian absolutist state. Thus developed the paradox that the state to which was entrusted the entire celebration of human liberty was really the one which with its coercive means strove to suppress it at its source, and that idealism—*lucis a non lucendo*—became the exponent of absolutism.

This union between idealism and absolutism did not continue in the subsequent history of idealistic political thought. The Hegelian doctrine had pretended to sanction the political and institutional status quo, whereas the idealism that followed attached itself to a movement in which for the first time, in conformity with all the exigencies of restoration in the larger sense, conservative and traditional elements fused with revolutionary: the movement of nationalism. The new nationalists were conservatives in the sense that the values for which they stood—race,

language, customs—were the product of a historical tradition; but they were at the same time revolutionary, because the existing political order did not give nations adequate recognition and it had to be overthrown by force to give national unity its political expression. Thus not only idealists of the type of Mazzini but also idealists of the Hegelian school, like de Sanctis and the two Spaventa brothers in Italy, dissociated the terms of the Hegelian compromise and espoused the cause of liberty and nationality.

This same compromise is represented today in the works of Gentile. That this is possible is, however, due not to reasons inherent in idealistic thinking, but to historical occasions and particularly to the very different attitude of present day nationalism from that of its formative period. Then the nation was an ideal force rousing itself in the name of liberty and self-determination against governmental oppression. Today the nations, which have definitively won political recognition, are increasingly becoming organisms economically and spiritually closed to the world outside them and at the same time aggressive and imperialistic. A thinker who applies to present nationalism the qualifications that liberals once attributed to their national ideals preserves, to be sure, the grammatical subject of his propositions but no longer the historical and real subject. Gentile thus repeats in his writings the old phraseology of the philosophers of the Italian Risorgimento although he is in fact thinking of something very different. It is in this way that the interpretation of idealist philosophy, as developed by Gentile, has become an integral part of present Fascist ideology. There exists, however, no intrinsic, logical or historical reason for making idealism responsible for the absolutist and nationalistic attitudes of certain of its partisans. If it is true that there are profound ideals incarnate in the institutions of history, such as nations and states, and that therefore idealism is right to dwell upon them and exalt the affection, the devotion, the spirit of sacrifice of individuals in their regard, it is also true that the ideals of the human spirit are not all comprehended in them and that to exalt them as exclusive objects of deification and worship is rather fetishism than idealism.

Apart from the Hegelian and neo-Hegelian deviations cited there is in most of the manifestations of modern idealistic thought the tendency to place the supreme values in human society not in the realizations already existing and in some manner institutionalized, but rather in the pro-

found spiritual exigencies that spur men on to create ever new forms and institutions in which they may adequately express the progressive character of their being. If in the course of the nineteenth century the national state represented this ideal over against the policed and legitimist states, today the national state is something that is beginning in its turn to be transcended in view of the higher ideal of a supernational and international society. The same may be said of the conditions under which Manchester liberalism was realized and surpassed. Since the nineteenth century English idealism has assumed a critical and polemic attitude toward the liberal order of the political society of the time. Thus Carlyle pillories with his most stinging criticism the mammonism of the capitalistic class, which under the cloak of liberalism hampered social legislation and the democratic progress of England. Later the philosopher T. H. Green pointed out how traditional liberalism with its formal respect for freedom of contract had come to consecrate an effective subjection of the working class to the capitalistic, and he therefore advocated governmental intervention to equalize really and not only formally the conditions of the labor contract. Thus he gave a new liberal-democratic direction to English liberalism by tempering those too individualistic and atomistic aspects which had made possible a certain social callousness and lack of sympathetic understanding and imagination in the Manchester school.

In Italy a profound revision of the political attitudes of idealism is taking place especially through the works of Benedetto Croce. Croce proposes to reconcile two aspects of the problem that at first sight seem to be in opposition: on the one hand, to assure active politics a certain autonomy in relation to ethics; on the other, to affirm that the dynamic forces of human history are essentially moral. His solution of the problem is by means of what he calls the dialects of distinct elements, by which politics is at once allied with and distinct from ethics; that is, it is a utilitarian activity conducted according to its own technical criteria but at the same time subordinate to and included within the scope of the moral consciousness. From this point of view political institutions, among which the state stands foremost, are susceptible to peculiar appraisals—economic, juridical, administrative and the like—but as actors and builders of history they are elements subordinate to the moral texture of human life. Thus the danger of a fetishistic adoration of them disappears, and the

interests of a sane conservatism harmonize with human aspirations toward reform and progress. A true protagonist of history is the spirit of liberty making use not only of states for its instruments but also of the transformation and even of the destruction of states to attain its universal ends. Croce's historical idealism does not stand for a mere respect for the past, for the status quo, but for an adhesion to the profound aspirations of humanity toward a future of more advanced liberty, citizenship and justice.

IDENTIFICATION is a term applied to the process of determining by confrontation of comparative analysis that a given person, object or idea is the one which is being sought. In the modern state in particular, with its intricate network of social relationships, governed by a multitude of rules which define the legal rights and responsibilities of the citizen, identification has become an increasingly important means of safeguarding civil rights. Its development is correlated with the growth of modern science, which has made possible the refinements in technique upon which good identification must be based.

The technique of identification has been so closely associated with criminal law enforcement that many assume that criminal identification is its whole domain. Before the scientific era the identification of prisoners accused of crime was difficult. Various devices were developed by the law as substitutes for witnesses to the crime or to protect the accused against bias or the fallibility of the senses. One of these devices was the ordeal, which threw the burden of identification on the Almighty; another was the confession, which made witnesses unnecessary and which led to the development of judicial torture. Where witnesses existed they were no doubt at times assisted in recognizing the accused by characteristics, such as physical defects and birthmarks, or by the amputations or brands which the law inflicted on certain offenders upon conviction. With the invention of photography an important step was made in the technique of identification, but it was not until Alphonse Bertillon devised his system of body measurements, standardized the criminal photograph and developed methods of individualizing the data by classification that identification was put on a scientific basis. Bertillon's anthropometric system was based on the fact that once physical maturity has been reached the dimensions of skeletal parts remain unchanged through life. His system made possible the identification of recidivists, which is important, since the criminal law prescribes heavier penalties for them than for first offenders. But the system had serious drawbacks. It was not applicable to physically immature persons and was not reliable in the case of adult women. In spite of this fact it was after its adoption in France in 1888 introduced in all parts of the world with excellent results and is still used in many localities in conjunction with fingerprints.

While Bertillon was perfecting his system, another and superior means of personal identi-

cation was being developed. The ridge patterns on the skin of the fingers had long been observed. Even before Malpighi in 1686 called attention to them, fingerprints had appeared in a magical role on occasional documents as far back as ancient China. In 1823 Johannes Evangelista Purkinje classified these patterns in nine groups. From 1858 on William Herschel, an English colonial administrator in India, used thumbprints to identify native workers in his charge. In 1888 Francis Galton became interested in fingerprints from the point of view of biological heredity and in 1891 he suggested a method of indexing them, thereby opening the road to their practical utilization. In the same year Juan Vucetich of La Plata, inspired by Galton, put into operation a system of classification based on a simple yet adequate principle and introduced fingerprinting in regular police practise. In 1897 Edward R. Henry proposed his elaboration of Galton's classification. Since then about twenty-five other methods of decadactylar classification have been established, most of them variants of the Vucetich or the Galton-Henry system. The former has been accepted in South America and in some European countries; the latter has found favor particularly in the English speaking nations. Most countries now possess national bureaus of criminal identification, where fingerprints are deposited. These collections are at times immense; the Bureau of Investigation of the United States Department of Justice, for instance, contained 2,802,606 cards on January 1, 1932; during the fiscal year 1931, 480,524 prints were received and 161,325 identifications made.

Once practical classifications of fingerprints had been developed, the Bertillon system was doomed as less effective, for the skin patterns remain unchanged from infancy to old age. Moreover criminals were known to leave fingerprints on the scene of the crime, but never their body measurements, a fact which made fingerprints useful beyond the identification of recidivists. The Bertillon system may still find use in case of persons who have lost hands or fingers, but even the latter may be identified by palmar impressions, which in late years have been studied and classified. Numerous systems of classifying single fingerprints have also been developed and methods perfected for the telegraphic transmission of prints. With the coming of television the exchange of such information will be facilitated.

Criminal identification may also be made by other methods. The records of dentists have frequently provided means of identification

where others have failed. Psychology has also been called into service since the turn of the century. The *modus operandi* system, devised by L. W. Atcherley and described by him in 1913, is based on the theory that professional criminals, like all craftsmen, develop habits in work reflected in their technique of operation. The police have thus been able to solve whole series of offenses committed before the one which led to a criminal's arrest. *Modus operandi* files exist in numerous police departments, but as yet no satisfactory system of filing large numbers in a national bureau has been invented. In recent years also experiments have been made with psychological tests, such as association tests and tests of emotional expression, as means of connecting a suspect with an offense; but these tests, which have often aided criminal investigation, have not yet found favor in the court room.

The identification of objects has also proved to be an important aspect of criminal investigation; for instance, the identification of a firearm by microscopic study of shells or bullets fired from it. The marks left by firing pins and barrels have proved to be almost as individual as fingerprints, and systems of classifying these traces or impressions are being developed. The identification of handwriting has not as yet reached the level of personal or firearm identification but is nevertheless making great strides. The value of expert testimony in all matters of identification depends of course on the honesty and competence of the expert.

Although identification has hitherto loomed largest in criminal justice administration, its greatest value in the future may perhaps be found in its use in civil life. Passports containing personal descriptions and photographs have long been in use and in 1912 Portugal introduced fingerprints on its passports. In some countries a *carte d'identité* more or less similar to a passport must be carried by all persons of certain categories. Photographs have also become important means of identifying owners of railroad or other tickets or certificates purchased at privileged rates. Banks occasionally fingerprint employees, and in civil service such prints are frequently required in order to prevent employment of persons with criminal records. They have also been used in military and naval services. In the United States, where the practise has been in force since 1907, the War Department possesses a classified file of about three million cards; the files of the Navy and the Marine Corps total two million. Maternity hospitals frequently

use footprints for the identification of infants, and recently experiments have been made in this connection with the stenciling of identification symbols by means of ultraviolet rays, a modern variant of branding.

The social importance of universal identification as a means of controlling and safeguarding the interests of both state and citizen has received most recognition in South America. In 1905 Vucetich sponsored the resolution relating to universal identification passed by the International Police Conference at Buenos Aires. He drafted the universal identification law, which was promulgated in 1916 in Argentina and abrogated within a year because of popular opposition; in 1931 a new law was drafted by Luis Reyna Almandos at the invitation of the government. Chile made fingerprinting compulsory in 1924 for all persons over eighteen years (since reduced to seven years) and in 1931 the Civil Registry Office was merged with the Central Identification Bureau.

Popular antagonism against the extension of fingerprint identification to non-criminals has deep roots in many countries, particularly in the United States, where the practise has occasionally prejudiced the rights of organized labor and where plans have been advanced for the fingerprinting of certain population classes alone, such as aliens. The proponents of universal identification have realized that an important means of counteracting such sentiments is not only the proposal of fingerprinting every person, but also the complete separation of the identification service used for civil purposes from bureaus of criminal identification. The importance of such a separation may be inferred from the fact that in the minds of many persons, expressed also in the legislation of most countries, an element of infamy or a criminal stigma attaches to fingerprints. In many jurisdictions they cannot legally be taken of petty offenders or of persons not yet convicted of crime, while in some the acquitted defendant has a right to the destruction of his fingerprints taken by the police. Another difficulty in the way of universal fingerprinting is a technical one. Experts have pointed out that existing systems of classification require considerable modification before they can be used successfully in the gigantic collections which such legislation would produce.

IDOLATRY. Idols are images used as abodes or receptacles for supernatural beings, gods, spirits of the dead or demons; they represent the fixation of spiritual power in a material object and differ from relics and fetishes only in being fashioned after the likeness of a man or animal, from sacred animals only in being inanimate. Idolatry cannot be fully explained by sympathetic magic, which is the belief that there is a close inherent connection between a person or thing and its image, so that whatever affects the image affects the original. A sacred stone may not resemble the god, yet what is done to it redounds to the god; a statue, however resemblant, is nothing but so much stone or metal and can be treated as such until it is consecrated. Sacred images of Ceylon and India are not revered until their eyes are formed and spirits are invited to enter by officiating priests. In China life is conveyed to the statue by putting small live animals into a hole at the back; then the eyes are painted and it becomes sacred. The giving of life to a statue is alluded to in *Revelation XIII*. In Egypt the important ceremony of consecration is called the "opening of the mouth." Mere resemblance is evidently neither sufficient nor necessary to establish a bond between the god and his material representation; it is the consecration that is essential. Resemblance is merely one of several qualifications, but one that has had such a profound influence on theology and politics that

idols stand in a class by themselves among objects of worship.

Images of animals go back to late palaeolithic times; the dark caves in which they have been found and the wounds they appear to have received leave no doubt that they had a ritual use. Human statuettes also existed in Aurignacian times, but it is not certain that they were idols. The beginnings of the later vogue of idolatry can be localized within narrow limits. Herodotus described the Persians as imputing folly to peoples who set up images and shrines and altars. Early Buddhist worship was addressed to the tumulus, tree and relics; the figure of the Buddha was deliberately left out. It was the Hellenistic school that introduced the latter as an object of worship in the first century A.D.; Hinduism later adopted the practise. Some Indian tribes are still without idols. Buddhism carried image worship to China and Japan. Varro declared that the Romans had served the gods more than 170 years without images. Tacitus and Caesar comment on the absence of idols among the Celts and Germans. Peoples outside the pale of the great civilizations either have no images to the present day or make no consistent use of them. On the other hand, the Egyptians were commonly representing gods in human form from about the second dynasty. The Sumerians had from the earliest times images Semitic in type and dress; this has led to the inference that they learned idol making from the Semites. Statuettes which can only be idols have been found in Minoan and Mycenaean sites. The expansion if not the origin of idolatry can thus be credited to an area adjoining the eastern Mediterranean.

Mummification, which was developed in the same area, indicates an anxiety to preserve the dead as completely as possible; the same idea may have suggested a close imitation of the deceased in stone, wood or metal. The Egyptian statue was formed as like the original as possible. The Greeks pursued a more generalized truth, aiming at anatomical correctness not of an individual but of an ideal body. Their artistic merit assisted considerably the spread of idolatry but at the same time undermined it, for their art eclipsed the ritual purpose and stimulated aesthetic appreciation instead of religious faith. In the period of decadence men accordingly returned to the uncouth and sometimes monstrous figures of archaic times as more suitable for worship. India subordinated art to theology; it was interested not in the human form or the personality, but in the attributes by the signs of which

gods are distinguished. India has a fondness for monstrosities such as numerous heads, arms and legs; gods with many limbs were known elsewhere in mythology and occasionally in art, but the artistic Greeks rejected these types. The late Roman Empire saw the influx of monstrosities, such as the Mithraic Cronus, compounded of many animals; but the western feeling was against them. Modern imagery has gone through a cycle comparable to the ancient. The works of Raphael are of too high artistic merit to stimulate devotion and have been followed by a return to a popular imagery.

Pure animal forms are uncommon, yet the earliest references to idols in the Bible are to the golden calf and the brazen serpent (*Exodus xxxii; Numbers xxi*). Idols animal and human are in every way equivalent to the deity and receive all the service bestowed on a sacrosanct king. They are bathed, anointed, clothed, crowned, fed, censured, lighted with candles, put to sleep and even provided with a consort. Frequently they are taken in procession. Various phases of this ritual are alluded to in the Old Testament and the Apocrypha (*Ezekiel viii: 10, 11; xvi: 17, 18; I Kings xii: 33; Epistle of Jeremy*). The ritual is still well preserved in India and Ceylon. As in the case of kings, equivalence tends to identity and idols come to be treated as if they were the gods themselves. Some images are considered more miraculous than others although theoretically of the same god. Idols are stolen from the enemy to deprive him of their assistance (Herodotus v: 83) and in consequence are chained to the wall. Conquerors remove the idols of the conquered. Idols become credited with human actions, such as nodding, shedding tears, sweating and speaking; impostures are sometimes perpetrated by priests, who provide the statue with mechanical devices for the performance of such acts. A little Burman village grew into a prosperous town because the local image perspired. The presence of miraculous images stimulates trade, which in turn encourages the continuance of the miracles.

The attribution of miracles to individual images has been carried furthest in Hinduism and Christianity. In Ceylon no statue has acquired an individuality. Buddhism put a limit on idol worship by not recognizing a soul. Leontius of Cyprus at the end of the sixth century argued that in family life a person's image, seal, even clothes, are constantly honored and that if images and crosses are placed in Christian churches it is not that they are regarded as gods

but as mementos. The official doctrine of the church is that images are a means of visual instruction as reminders of religious truths and as stimulants to devotion. In practise, however, the masses lapse into idolatry, making vows not so much to the Virgin or a saint as to one particular image, such as the Virgin of Lourdes or the Virgin of Halle. The Greek church does not allow statues, but the cult of icons, or pictures, has been carried to extremes; they are everywhere even in shops, banks and railway stations. The Christian church has no cult images of God the Father, but only of those who have lived in the flesh: Christ, Mary and the saints.

Idolatry has stimulated anthropomorphism. Before the introduction of idols gods appear to have been spoken of in human terms but to have been so far from being primarily human that an Indian writer of the sixth century B.C. found it necessary to explain why they are spoken of as having human attributes. Idols by always presenting gods in human or animal form fix that form as their proper one. They cease to be vague powers and become supermen. A concrete personality on which to fix the emotions of hope, fear, veneration, anger and revenge is more readily grasped by the masses; hence its success. Originally the idol was merely the receptacle of a power or a spirit and the means of bending the spirit to man's will. This point of view still persists among the Christian masses in spite of the teaching of the church—as witness the Tamil fishermen who immersed a statue of St. Anthony up to the neck in the sea and threatened to drown it if it did not grant them better fishing. The idol thus provides a convenient scapegoat on which the worshiper can vent his disappointment, whereas he would feel helpless if he thought himself confronted by an impersonal and inexorable nature. Among the educated classes of the great religions such props are less necessary; the other emotions recede into the background and veneration is dominant. Images then provide a visible object on which to fix that idealism which is not satisfied by the real world.

IDRĪSĪ, ABU-'ABDALLĀH MUḤAMMAD IBN-MUḤAMMAD AL- (c. 1100-66), Moslem geographer. Al-Idrisi was educated at Cordova and after traveling extensively for many years in Asia Minor, Egypt, Morocco, Spain and Portugal spent a long time at Palermo at the court of his Norman patron, Roger II. There in 1154 he completed *Kitāb Rujār* or *Nuzhat al-Mushtāq fī Ikhtirāq al-Āfāq* (Book of Roger, or the recreation of him who wishes to travel through the countries), one of the most important geographical works of mediaeval times. It not only sums up the chief features of such preceding works as those of Ptolemy and Mas'ūdī but supplies for the Moslem world as well as western Christendom a remarkable fund of information based primarily upon original reports submitted by emissaries whom he had sent to various countries to secure data. The geography of Italy, France, Illyria and Germany was practically unknown to previous Arabic geographers. In his critical collation of the material Idrisi showed a noteworthy breadth of view and grasp of scientific facts, such as the roundness of the earth. Some of the seventy-one maps in this work represent despite obvious defects the best products of early Moslem cartography. The work as a whole suffers, however, from an insistence upon a rigid climatic division and a tendency to disregard all other dividing lines, whether physical, linguistic or political, which are not in harmony with it. Al-Idrisi constructed for Roger a celestial sphere and a disk shaped map of the world, both in silver, and wrote for William I of Sicily *Kitāb al-Mamālik* (Book of kingdoms), of which only an extract remains. His writings found no early Latin translator and

therefore there are but faint traces of their influence upon European thought.

PHILIP K. HITT

Works: The text of *Nuzhat* has been published only in part. A superficial synopsis appeared in Rome (1592) and was translated inaccurately into Latin as *Geographia nubensis* by Gabriel Sionita and Joannes Hesronita (Paris 1619). A poor French translation of the entire text was made by Amédée Jaubert, *Géographie d'Édrisi*, 2 vols. (Paris 1836-40). Other editions and translations have been made of certain sections; among them are *Description de l'Afrique et de l'Espagne* by R. P. Dozy and M. J. De Goeje (Leyden 1866), and *L'Italia descritta nel "Libro del re Ruggero"* by M. Amari and C. Schiaparelli (Rome 1883). The best translation of the portion on Spain is by Antonio Blázquez, *Descripción de España* (Madrid 1901). The extract of *Kitāb al-Mamālik* referred to is available only in the Ḥakīm Oghlū, 'Alī Pasha Library, Istanbul (no. 688).

(Paris 1840-83) vol. ii, pt. i, p. cxxiii-cxxii, cccx-cccxvi; Carra de Vaux, Bernard, *Les penseurs de l'Islam*, 5 vols. (Paris 1921-26) vol. ii, p. 9-13. For maps see "Idrisi-Atlas" in *Mappae arabicae*, ed. by Konrad Miller, 6 vols. (Stuttgart 1926-31) vol. vi.

IGLESIAS POSSE, PABLO (1850-1925), Spanish socialist. Iglesias was a printer by trade and intellectually self-taught. He was one of the Madrid group of labor unionists and radicals who were the pioneers of the Spanish Socialist party. Iglesias was a member of the International Workingmen's Association (First International) through his membership in the Alianza de la Democracia Socialista, which had been organized in Spain in 1868 under the influence of the Garibaldian Fanelli, the coworker of Bakunin. Iglesias, however, was not influenced by anarchist ideas and did not deviate from Marxism; he was an influential force in the typographical section of the Madrid Federation of the International. In 1872, when the Spanish delegates to the congress of the International at The Hague leaned to the side of Bakunin in his struggle with Marx at the time of the split between socialists and anarchists, Iglesias repudiated their action and was instrumental in the formation of a Marxist Socialist party. In 1886 he began the publication of the journal *Socialista*; and in 1888 he formed the Unión General de Trabajadores, a labor union organization decidedly under the influence of the Socialist party; the *Socialista* became the organ of both the union and the party. Iglesias was the undisputed leader of the party, its organizing and tactical genius

He was imprisoned several times by the government. In 1910 he was elected to the Cortes, where he ably expounded the official Socialist policy. During the World War and the early post-war period the Socialist party grew in numbers and influence, still under the leadership of Iglesias. His leadership, however, was challenged by Left wing elements influenced by the Bolshevik revolution in Russia and in 1921 the party split, as did all parties of the Socialist International, between socialism and communism. Iglesias remained loyal to orthodox Marxism and adhered to the International Union of Socialist Parties in opposition to the Third, or Communist, International. Iglesias was essentially an organizer and man of action; his writings are unimportant.

IGNATIUS OF LOYOLA. *See* LOYOLA, IGNATIUS OF.

IHRER, EMMA (1857-1911), German socialist and labor leader. Emma Ihrer was born in Silesia; in her early twenties she went to Berlin, where she made a precarious living for herself and her widowed mother by working as seamstress. Here she first came in contact with the labor movement, which was at that time severely hampered by Bismarck's antisocialist laws. Despite her early Catholic training the militancy of the movement appealed to her indomitable spirit, which resented the oppression to which the women factory workers were subjected. The Social Democratic party attempted to organize these women workers, although the law prohibited participation of women in political organizations, and Emma Ihrer became a tireless agitator and organizer. She was among those who formed in 1885 the Verein zur Verteidigung der Interessen der Arbeiterinnen which, after a number of successful public demonstrations demanding increased wages, a shorter workday, Sunday rest for women workers, particularly in the needle industry, and woman suffrage, was dissolved by the police. With the repeal of the antisocialist laws in 1890 the political and economic organization of working women grew rapidly, and Emma Ihrer became one of the most influential leaders of the movement. She founded

and edited the *Arbeiterin*, the first woman's labor paper in Germany, which was taken over by the Social Democratic party and continued to appear as the *Gleichheit* with Klara Zetkin as editor. Emma Ihrer insisted that woman's emancipation could be accomplished only through the socialist labor movement, a conviction which she developed ably in *Die Organisationen der Arbeiterinnen Deutschlands* (Berlin 1893) and *Die Arbeiterinnen im Klassenkampf* (Hamburg 1898). At the time of her death Emma Ihrer was president of the Artificial Flower and Feather Workers' Union of Germany and the editor of its organ, *Blumenarbeiterin*.

ILBERT, SIR COURTENAY PEREGRINE (1841-1924), English jurist. From academic life in Oxford Ilbert passed to the legal membership of the council of the governor general of India, a post which he retained from 1882 to 1886. He endeavored, with Lord Ripon's approval, to eliminate racial discrimination in the administration of criminal justice by extending to district magistrates and sessions judges of Indian race power to try European offenders; this evoked deep appreciation from nascent nationalist feeling but aroused bitter hostility in the European commercial community, which had to be conciliated by granting to such offenders the privilege of trial by juries half European in composition. As a result of his important work in drafting Indian laws on his return to England he was appointed in 1886 as parliamentary counsel with responsibility for drafting governmental bills, and the wide knowledge of parliamentary procedure thus acquired bore fruit in his selection in 1902 as clerk of the House of Commons, where he remained until 1921. His grasp of Indian constitutional law led to the determination to reduce to code form the mass of English legislation as to India, and his labors are the foundation of the important Government of India Act of 1915 consolidating forty-seven acts from 1770. His own work as draftsman, his influence as chairman of the Statute Law Committee and his lucid and effective exposition of the principles of his art had powerful influence on the technique of both English and colonial legislation, while his active interest and support contributed largely to the successful establishment of the *Journal of*

Comparative Legislation as a means to the comparative study of the laws of the British Empire and foreign countries.

ILLEGITIMACY

SOCIAL ASPECTS. While an illegitimate child is ordinarily considered to be one born to an unmarried woman, the term applies also to the child of a widowed or divorced woman when the husband could not have been the father and to the issue of void or voidable marriages in the absence of countervailing legislation. The term "born out of wedlock" may have little more than technical significance in communities where custom renders moral certain departures from premarital chastity, as between betrothed couples. Illegitimacy in some form is a universal social phenomenon, and law and custom everywhere take account of it. Marital institutions and sex mores, however, differ so widely and are so differently integrated with economic, moral and religious practises as to give it a bewildering sociological variety. Like divorce, it is understandable only in the light of its entire sociological setting in each community; it cannot therefore be viewed as an index of sex morality.

Among primitive peoples a woman with a child finds her chances of marriage enhanced, unaffected or seriously blighted depending on the traditions of her tribe. Among numerous tribes permitting premarital license the unmarried mother is in such disgrace that she may be killed or severely punished, while her child is almost certain to be destroyed at birth; elsewhere she is more eagerly sought after as a spouse because her fertility has been demonstrated. In some societies no line is drawn between the children born to wife, concubine or slave, provided the master acknowledges them; elsewhere only the children of the first wife are regarded as legitimate. Where sex freedom is granted to wives and where wife lending and similar customs prevail, the offspring are all regarded as legitimate; whereas in other societies the wife may be summarily executed for adulterine bastardy.

Christianity sought to stamp out premarital

unchastity by making it sinful and by placing the unmarried mother under severe condemnation. It was no easy task, however, to bring about a degree of harmony between sex mores of long standing and the ideals of an ascetic religious morality. Viewing woman as the chief source of sin Christianity tended to degrade motherhood, to accentuate masculine supremacy and to maintain a double standard of morality. It thus inflicted an often unbearable cruelty upon the unmarried mother and an almost certain degradation upon her offspring. In mediaeval and early modern times the mother was often required to confess her sin before the congregation in both Catholic and Protestant communities; she was sometimes fined, sometimes publicly whipped, sometimes placed in the stocks, and the child was neglected and socially ostracized, while the father suffered little or no penalty. Such severe treatment of the mother of an illegitimate child compelled concealment, abortion, maternal mortality and infanticide. In 1777 Frederick the Great wrote to Voltaire that the largest number of the executions occurring in Germany were of girls who had killed their infants. Severity of treatment and its multiplication of unnecessary evils continue in some areas but are giving way to the more humane methods of a rationalistic morality.

The extent of illegitimacy varies widely even among nations of European culture. Statistics are unreliable because of concealment and the registration of the illegitimate as legitimate. Comparisons of country with country are inexact. Illegitimacy rates are stated usually as a proportion of total births but sometimes as a rate per 1000 single, widowed and divorced women of child-bearing age. Both methods have their advantages; one showing whether illegitimate births represent an increasing or decreasing contingent of all births and the other whether illegitimacy is increasing or decreasing in relation to its opportunities.

A compilation of official data by the Children's Bureau of the United States Department of Labor showed that the number of illegitimate births in Europe in 1914, omitting those in Russian Finland, Poland and the Balkan States (except Rumania), exceeded 900,000. The percentages for illegitimacy for Norway, Sweden and Italy in 1926 were respectively 6.54, 14.57, 4.96; those of Belgium, Denmark, Germany, Chile and Uruguay in 1927 were 4.6, 11, 12, 35.07, 28.21; those of England and Wales, of Scotland and of Ireland in 1928 4.5, 7.4, 4.6.

The highest rates of illegitimacy officially reported are those of Jamaica (1924 to 1928) and Panama (1925), which exceeded 700 per 1000 births between 1921 and 1925; extraordinarily high rates are found also in Cuba and Central and South America. These wide differences have been of long duration. The World War led to a considerable increase in number of illegitimates in England and Wales; the wartime illegitimacy ratio to total births increased also in France and Germany, although the actual number of illegitimate births declined in those countries and in Finland, Scotland, Italy, Australia and New Zealand. Thus the annual average numbers of illegitimate births in Germany were: 1911 to 1915, 177,645; 1916 to 1920, 136,923; 1921 to 1925, 154,592; while the ratios per 1000 total births were for the three periods respectively 100, 113 and 110. The statistics of illegitimacy have manifested no general tendency to increase or decrease during fifty years, although they decreased somewhat in most European countries in the two or three decades before the war and have increased since then. The rate per 1000 total births was distinctly higher in 1925 than in 1875 or 1880 in Austria, France, Germany, Sweden, New Zealand and Finland; it was slightly higher in Denmark and Australia. It had fallen in Norway, England and Wales, Scotland, Italy and Holland. The Japanese rate has fallen sharply from 116 for the years between 1891 and 1895 to 78 per 1000 births for the years between 1921 and 1925 and to 67 in 1928.

In interpreting these figures it should be noted that in view of the general decline in the total number of births a lesser decline in the number of illegitimate births would give an increasing ratio. Moreover decline in the birth rate increases the proportion of first born, among whom the incidence of illegitimacy is much higher than among the later born. The illegitimacy rate may therefore be an increasing proportion of all births even though it is declining if calculated per 1000 unmarried women. It may also be affected by changes in the relative ages of unmarried women. The completeness with which illegitimate births are recorded has probably increased in various countries. This is true of the United States, where annual data for illegitimacy since 1917 for an increasing registration area are available. These show for 1928 a total of 63,942 illegitimate births, excluding those of New Mexico, Nevada, South Dakota and Texas, states not in the registration area, and those of California and Massachusetts, where no statement con-

cerning the legitimacy of the child is required. In 1928 the rate was 30.9 per 1000 births for the entire area, 16.7 for all whites, 18.2 for native whites, 6.7 for foreign whites and 136.6 for Negroes. The rates per 1000 total births have increased since 1917 for all population classes by closely similar percentages. The Negro rate has been from eight to ten times that of whites, accounting in recent years for about one half the total number. Although the rural rate for the entire registration area has been slightly higher than the urban, the reverse is true for all but a few of the states and for all population classes except the colored. In continental Europe the urban rate is now distinctly higher than the rural. The urban excess reflects the presence of a greater number of young, unattached persons of both sexes, the anonymity of city life, the absence of community social controls and the large numbers of young women engaged as domestics, waitresses and industrial workers.

The infant mortality rate is usually from 50 to 100 percent higher for illegitimate than for legitimate births. The death rate of mothers from causes connected with pregnancy and childbirth is found to be about twice as high for unmarried as for married mothers. The illegitimate infant death rate is relatively higher in urban than in rural areas in spite of greater hospital facilities and social welfare agencies. Moreover English and Norwegian data reveal that the ratio of illegitimate infant deaths to legitimate is higher in the second month than in the first and still higher in the third. The causes of the higher mortality of illegitimates may be in part the immature ages of some of the mothers but are mainly the generally adverse economic and social conditions surrounding both mother and infant together with ignorance, secretiveness and wilful neglect. Debility and marasmus are much more frequent among illegitimate infants, and the proportion of deaths from intestinal disorders is notably high. It is difficult for the police to distinguish between malicious maltreatment and stupid ignorance on the part of the mothers. German data for 1902 to 1927 show that illegitimate infant mortality declined fully as rapidly as that for legitimate births, being in 1927 less than the mortality of the latter in 1914.

Illegitimacy is an important cause of infanticide, abortion, premature births and stillbirths. Widespread infanticide led the church in the sixth century to establish in Italy the first foundling asylum and in the twelfth century to utilize the *tour*, or turn box, to receive the child without

revealing the mother's identity. Miscarriages, including abortions, and premature and stillbirths are considerably greater for illegitimate than for legitimate births. The number of stillbirths is doubtless increased by maltreatment of the infant during or immediately following birth. Moreover illegitimate births are predominantly first births, among which stillbirths are generally high. Not only are the mothers often extremely young but they are more likely to continue at regular work until parturition is imminent; and syphilitic infection is markedly more frequent among illegitimate than among legitimate mothers. Among other effects of illegitimacy are delinquency, crime, destitution, prostitution, venereal disease, further illegitimacy and cruelty to mothers and children.

In those parts of Europe and America where illegitimacy suffers social stigma its causes must obviously be those conditions which result in unregulated premarital intercourse. They may be classed as personal and social, although the former result largely from the latter. Unmarried mothers are sometimes either feeble-minded or psychopathic; some suffer from ignorance of simple biological facts, high sexual suggestibility and lack of industrial proficiency and personality development. The social causes center in the character of home life and of parents but often include also neighborhood and community mores. Parental and home standards influence profoundly ideals of sex and family life, extent of education and vocational training, recreation, companionship and employment. Social work inquiries have revealed illegitimacy closely associated with poverty; with drunken, quarrelsome, unsympathetic or immoral parents; with broken homes, unsupervised recreation and early employment. The impossibility of marriage during those years when the sex impulses are most powerful and little understood is an important factor. The higher rate of illegitimacy among the lower classes is no doubt due in part to the better knowledge of birth control among the upper classes and perhaps also to more facile abortion.

Religion seems to have little relation to present illegitimacy rates. Catholic Austria and Protestant Sweden have the highest rates in Europe, while Catholic Ireland, Protestant Holland and England and Greek Orthodox Russia (before 1917) have rates among the lowest. German data show considerably less illegitimacy among Jews than among other religious groups but with some tendency to increase during the

last generation. Nor is climate a measurable factor. Occupation and social class are vastly more important. Everywhere the ratio of domestic and agricultural servants having illegitimate children is large and rates are high for women workers in hotels, restaurants and industry. The ratio was large among indentured servants of the American colonies, among Indians in contact with whites and among Negro slaves. In fact it has been a feature of the spread of white domination throughout the world, often associated with slavery or concubinage. It is an accompaniment of the superposition of races and classes, as in military invasions and conquest, and of periods of social upheaval, such as war and revolution. In the rural sections of Austria, where illegitimacy is the most general in Europe, it is associated with late marriage, with large estates where only members of the family and domestics reside, with absence of social stigma and with legitimation by subsequent marriage and recognized conventions governing intercourse of unmarried persons. In America bastardy was relatively common under pioneer conditions, where women because of their scarcity were little handicapped by the possession of illegitimate children. In northern Europe it is associated with conventionalized premarital intercourse of betrothed persons, partly to test the fruitfulness of union; it appears also to be associated with the equality of the sexes and the social and economic independence of women. In Soviet Russia, where the latter conditions prevail, there seems to be little or no social stigma attached to children born out of wedlock. In Central and South America and the West Indies, in some parts of which illegitimacy is the rule, it is associated with mixed white and Indian or Negro populations, in which the mass mores reflect less the traditional morality of the original racial elements than a morality springing from racial miscegenation under frontier and colonial conditions.

Little governmental care and protection of illegitimate children were manifested until the World War. In English speaking countries especially it was the rule for white mothers to abandon, give away or otherwise dispose of their illegitimate infants; colored mothers have generally followed the opposite course. While the mother's confinement was mollified by a restricted hospital service, by "rescue homes," such as those of the National Florence Crittenton Mission and the Salvation Army, and by child welfare societies, private maternity homes

too often found profit in disposing of her infant to a baby farm or foster home where his life was likely to be short and harrowing. Foundling asylums, orphan homes, child placing agencies, maternity homes and similar agencies are now, however, increasingly subject to public licensing and inspection. Illegitimate children are viewed as future citizens, workers and soldiers and as worthy as the legitimate of care and training. The state is finding it advantageous both economically and culturally to assume official guardianship over them. Legislation, formerly concerned primarily with protecting the taxpayer, increasingly aims to keep mother and child together, to enforce paternal responsibility and to insure the health, protection and education of the child.

FRANK H. HANKINS

LEGAL ASPECTS. The law dealing with the child born out of wedlock has throughout history reflected to a considerable degree the changing mores concerning illegitimacy. It is only necessary, however, to consider the scope of possible regulation with respect to rights of support, inheritance, filiation or legitimation to conclude that the law has rarely been consistent. Not even all illegitimate children have been treated alike. Quite generally in both ancient and modern times adulterine or incestuous bastards have received far less favored treatment than the ordinary child born out of wedlock. In the latter class have been many who have been bastardized by purely technical requirements of marriage laws. Such results have followed particularly when degrees of prohibited consanguinity or affinity have been extended too far or where divorce laws have been in sharp conflict. Finally, it must be remembered that the individualism of the private law, which became very marked in the nineteenth century, has often left some degree of choice to the parent of an illegitimate child. Since a growing freedom of testation has made it possible for a man to leave his property as he wished, an illegitimate might be benefited no less than a total stranger. Where the law recognized the institution of adoption, the father might sometimes make an illegitimate child a member of his own household.

Because of the peculiar structure of the early Roman family, based as it was on the principle of agnation, the position of the illegitimate child was unfortunate in the ancient Roman law; he had neither father nor mother. But with the development of the principle of cognation the il-

legitimate child came to have rights of support and succession with regard to his mother. The attachment of the child to his mother's family was due to the rise of the *jus naturale*, under which the principle of cognation came to be regarded as the basis for kinship. The natural child remaining a stranger to his father became along with the legitimate child a cognate of his mother. The betterment of the position of the illegitimate child was thus merely the logical consequence of the structure of the Roman family.

It was, however, the law of the Christianized empire, not of pagan Rome, that became most influential. Constantine suppressed all rights of illegitimate children against their mother except in the case of those born in concubinage, which had become a recognized institution. Illegitimate children were now classed according to the degree of guilt of the union which produced them, and the child's property rights were dependent on the class from which he came. Illegitimate children were of two main categories: first, those *ex damnato coitu*, of which there were two classes, the incestuous children and adulterine children; and, second, *liberi naturale*, or natural children proper, of which there were three classes, those born of a concubine (*retenta in domo*), those born in prostitution (*vulgo quaesiti*) and those born of any other union (*spurii*). The most important aspect perhaps of the legislation of Constantine was his introduction of the doctrine of legitimation by subsequent marriage. Two other methods of legitimation came into practise under the law of the empire. The first was by special imperial decree (*per rescriptum principis*) and the other was by presentment to the curia (*per oblationem curiae*). Under the legislation of Justinian the position of the children of concubines became very favorable and their rights of inheritance greatly increased.

Under early Germanic law bastards had to be cared for and supported by the mother under the *maegth*, or kinship group. The lack of betrothal prevented the father from exercising *mundium* over a free born concubine or her child. Nevertheless, the Germanic house lord could constitute his household as he wished; and if he received an illegitimate son into it, the latter commonly had rights of inheritance along with the legitimate sons. This certainly was true of the Germanic law in the Christian period. Under Lombard law, which is most explicit, the position of a natural son was especially favorable. He not only shared in rights of inheritance

but in wergild and the bethrothal price of a sister.

In the Middle Ages under Christian and feudal influences bastards were largely deprived of the ordinary rights of man in the continental countries. Under many law books the bastard became little better than an outlaw. The feudal lord often treated him as a serf. He sometimes lost the right to inherit even from the mother. Mediaeval legal theory, however, generally maintained that the illegitimate child had a right to support. So too did the canon law, which moreover came to recognize the doctrine of legitimation by subsequent marriage, extending it to all cases of parents who might have married at the time of conception.

The common law of England was ruthless in its denial of rights to children born out of wedlock. The bastard was in every sense of the term *filius nullius*. At common law the illegitimate child was completely isolated from his parents; even though he was born of unfree parents he was free himself. At the outset neither parent had any right to the custody or guardianship of the child. The law recognized no legal relationship between the mother and child, far less between the father and the child. In no way could the child born out of wedlock inherit from his father or even from his mother. He had no heirs but those of his own body; if he died without lawful issue, any real or personal property might escheat to the crown. He had no rights of support against either of his parents. Nevertheless, the bastard was under none of the harsh disabilities of civic degradation to which he was subjected elsewhere. Under English law, however, following the Statute of Merton of 1236, legitimation by the subsequent marriage of the parents was not recognized.

In England from early times the illegitimate child was cast upon the parish for support and was cared for like any other vagrant or poor person. The first right to support came as the result of the parish's unwillingness to carry this heavy burden. The Poor Law Act of 1576 (18 Eliz. c. 3) put the duty of maintenance on both parents. Later legislation, however, shifted the burden to the father (acts of 1809, 1844 and 1872).

From the Middle Ages until modern times no very great improvement in the legal position of the illegitimate child occurred except as to the removal of civic degradation. Indeed the first of the great modern civil codes meant a distinct retrogression. Under the *ancien régime* in France in the regions of both written and customary law

the illegitimate child had the right to seek out his father, at least for the purpose of establishing the right to support. But the *Code Napoléon* declared in its famous article 340: *La recherche de la paternité est interdite*. With the investigation of paternity forbidden, neither the unmarried mother nor the illegitimate child had any rights, and thus the law of France remained until 1912.

Under the present law in France the court can inquire into the question of parentage, but only in cases of seduction, abduction, notorious concubinage or where there has been an admission by the father. A filiation action can be brought by the child and during his minority by the mother. In most cases an incestuous or an adulterine child cannot inquire into his parentage. If a filiation order has been made or the child has been recognized, the child takes the name of the father if recognized by him; if recognized by the mother alone, her name. In the case either of judicial filiation or recognition the parents are under a duty to support the child; the child succeeds to his parents and they succeed to him. This, however, does not give him rights of succession to the ascendants of his mother and father. Provision is made in the code for the voluntary formal recognition of the child by either parent, but such recognition does not affect the other parent. Generally recognition cannot be made for the benefit of an incestuous or an adulterine child. If a child is neither recognized nor filiated he still has rights of support against anyone who pretends to be his parent. The amount that the illegitimate child can take on intestacy is dependent upon whether his parents have legitimate children. There is a provision for the legitimation of a child born out of wedlock by the subsequent marriage of the parents. The child, however, must have been recognized before the marriage. Such legitimation carries with it all the effects of legitimate birth.

It is provided by the German civil code, which in this respect has followed the German common law, that in regard to the mother and her relatives the illegitimate child is in the legal position of a legitimate child; further in regard to the father the child born out of wedlock may be declared legitimate upon his petition by a government declaration, the child thereby acquiring all the rights of legitimacy. There is a provision that to this petition the consent of a child or his guardian is necessary and, if the child has not reached twenty-one, the consent of the mother also. If the marriage of the parents was prohib-

ited at the date of the child's conception, there can be no declaration of legitimacy. The child can obtain the right to support and maintenance against the father even if the latter does not establish his legitimacy, and this through the judicial establishment of paternity or through voluntary recognition. The duty of the father to support precedes that of the mother. Legitimation can also take place through subsequent marriage.

The laws of the Scandinavian countries in regard to children born out of wedlock are in advance of those of most countries. The Norwegian law, passed in 1915, places the burden of establishing paternity and of fixing the maintenance on the state rather than on the mother. The law calls for the compulsory reporting of the pregnancy by the physician or midwife consulted and of the birth of the child out of wedlock by the physician, midwife or mother. Thereupon the proper officials summon the man named as the father, who if he denies the paternity must institute proceedings to establish the true paternity or be held liable. The illegitimate child is placed in the same position in regard to his father as in regard to his mother; the child is entitled to the name of the father and to maintenance and education from both. The type of support and education is determined by the economic position of the more favorably placed parent. The law provides for minimum sums which are to be paid for the maintenance of the child to the sixteenth year; the local government official is charged with the supervision of these payments and given remedies for the collection thereof. Careful provisions are made against the father's migration before he has completed his payments. If the father dies before full payment has been made, the balance is a charge on the estate after the creditors have been satisfied, although in no case can a child born out of wedlock receive more than a legitimate child. Unless the child's parents have married, he has the same rights of inheritance as a legitimate child; the parents have a similar right in regard to the child.

The Swedish law of 1917 gives the child born out of wedlock no right of inheritance from the father except in the case of "betrothal children." Under an amendment of 1928, however, the father may by declaration stipulate that the child shall inherit from him. The responsibility for support is placed on both parents. Unless otherwise ordered by the court the mother has the custody and legal guardianship of the child. It is provided that the parent not having the care

of the child is to meet the maintenance expenses. A woman bearing a child out of wedlock is placed under a duty to report her condition to the "guardian official" of the parish, who designates a suitable person to act as guardian for the child. It is the duty of the guardian to see that the child's rights are protected, to proceed to determine the paternity and to collect the support. In Sweden the burden of proof in regard to paternity is on the person instituting the proceeding and not on the alleged father, as in Norway. Under the laws of Soviet Russia no legal problem of illegitimacy exists.

In all but a very few countries legitimation by the subsequent marriage of the parents is now recognized, although adulterine or incestuous children are generally excepted. The doctrine was finally introduced into England by the Legitimacy Act of 1926, which gave such a legitimated child all the rights of inheritance which he would have had if born legitimate. The same act made it possible for an illegitimate child to inherit from his mother and for the mother to inherit from the child. Legitimation by subsequent marriage had been introduced into the British dominions much earlier either by the continuance of the continental codes which contained the doctrine or by special legislation, as in all the states of the Australian Commonwealth and New Zealand, which indeed had shown the way as early as 1894.

The number of countries which assimilate closely the relation of mother and illegitimate child to that of mother and legitimate child is still small. Indeed as a principle it prevails primarily in the Germanic countries. Thus Austria and Switzerland may be mentioned in addition to Germany and the Scandinavian countries. The voluntary acknowledgment of an illegitimate child now generally entails some rights of inheritance; and sometimes even where the acknowledgment is effected only by judicial proceedings. In most places, however, the establishment of the putative father is still mainly for the purpose of securing support for the illegitimate child. There is some provision for compelling support in practically all countries. The exceptions are constituted primarily by those very few countries which still prohibit an investigation of paternity. The most important exception to the right of support is the *exceptio plurium concubentium*, which generally prevents the affiliation upon which the right is predicated. But even this exception is abrogated in some countries, as, for example, the Scandinavian coun-

tries, Soviet Russia and some parts of Canada.

In the United States there may be found illegitimacy laws of practically all known types from the most backward to the most advanced. At the one extreme are the laws of a few states, such as Texas, Louisiana and Virginia, which, since they ordinarily interdict the investigation of paternity, make it impossible for an illegitimate child to secure support. At the other extreme are such liberal laws as the Minnesota law of 1917, which charges the board of control of the state with safeguarding the interests of the illegitimate child to the extent of securing for him "the nearest possible approximation to the care, support and education that he would be entitled to if born of lawful marriage," and the North Dakota law of 1917 (followed by Arizona in 1921) which declares that every child is the legitimate child of his natural parents.

The oldest type of American illegitimacy law was simply the bastardy proceeding, historically connected with the English system of poor relief. While improved forms of bastardy or affiliation proceedings are now generally available they often leave much to be desired, since the sums awarded for support are usually low. Frequently the bastardy proceedings are criminal in nature, as under the old Massachusetts and Pennsylvania laws. In states where the non-support and abandonment laws apply to both legitimate and illegitimate children criminal proceedings are also available to enforce the obligation to support. The advantage of imposing criminal sanctions is that it enables the system of probation to be used and makes possible the extradition of fathers who have absconded to some other state. A very favorable type of law, which is primarily designed to enforce maintenance, is the Uniform Illegitimacy Act, which since its drafting in 1923 has been adopted in Nevada, New Mexico, New York, North Dakota, South Dakota and Wyoming.

The continuous tendency of American legislation, however, has been to depart more and more from the common law. The relationship of the illegitimate child to his mother has been made to approximate the status of lawful parent and child, and most American states have by statute given the illegitimate child a right to inherit from or through his mother, sharing alike with her legitimate children. On the other hand, paternity is generally established only for the purpose of securing support. In some states a right of inheritance is given in case of acknowledgment by the father in the absence of ex-

pressed legitimation. There is particularly great variety in the possible methods of legitimation. In almost all of the states there is recognized legitimation by the subsequent marriage of the parents either with or without recognition by the father. In a minority of states legitimation by the father in the absence of marriage may be accomplished in many formal as well as informal ways: by proceedings before various courts in Alabama, Georgia, South Carolina, North Carolina and Tennessee; by notarial acknowledgment or filing in a notary's office in Delaware and Louisiana; by recording an instrument like a deed in Michigan. In several states the father may legitimate the child by public acknowledgment or by adoption. American practise particularly has made use of the procedure of adoption, although it was unknown to the common law and, while known in the civil law countries, has rarely been used there in cases of illegitimacy. Another characteristic of American law has been the great amount of legislation which is intended to obviate technical illegitimacies. Thus the issue of many marriages which might be voidable or void for many reasons, such as nonage, idiocy, insanity, consanguinity, affinity or bigamy, are often declared to be legitimate. The miscegenation laws, however, contain no such saving provision. The issue of common law marriages are of course legitimate.

In several states the expression "child born out of wedlock" has been substituted for "bastard" or "illegitimate child" in all laws and public records. It is also sometimes prescribed that birth certificates omit reference to the fact of illegitimacy. Of greater material importance are the laws of Maryland, North Carolina and South Carolina which prevent a mother and child from being separated during the nursing period; such separation is a particularly important factor of high infant mortality among illegitimate children. A variety of other laws also benefit illegitimate children. In Michigan, Nebraska and Tennessee mothers' aid laws specifically authorize aid to unmarried mothers, a result that has been achieved in some other states by judicial construction. Workmen's compensation acts in twelve states apply to illegitimate children. In Nevada the acts apply to any illegitimate child; in Colorado, Idaho, Indiana, Kentucky, Louisiana, New Mexico, New York and Vermont only to acknowledged illegitimate children; and in Montana, Oregon and Washington only to those who have been legitimated prior to the injury.

Despite the legislative steps already taken there is a considerable social lag in the illegitimacy problem. The entire aspect of the welfare of the mother and child has been neglected; the question of financial support alone has received general attention.

ILLITERACY. *See* LITERACY AND ILLITERACY.

IMITATION. The concept of imitation was first given prominence in the writings of Walter Bagehot, Gabriel Tarde and Edward A. Ross, who used the term as a general principle to explain the spread of social beliefs and practises and to describe social processes now defined in terms of diffusion and syncretism of culture. Bagehot, who applied the term to man's universal tendency to follow patterns of behavior set before him, believed that "the imitative propensity" insured uniformity. Tarde held imitation with its correlated processes of opposition and adaptation to be the fundamental social process which accounted for the spread of fashion, crime, education, new inventions and other social patterns. For him imitation was the human social particular of the universal law of repetition found everywhere in nature. He ascribed invention to the conflict and combination of

items imitated or learned and formulated the laws of imitation as logical imitation, derived from reason and deliberation, and extralogical imitation, which is motivated by feelings, emotions and the desire for prestige and status. Ross, who drew heavily upon Tarde, depicted and classified several types of imitation: fashion, the imitation of innovations in dress or manners; convention, imitation of present day standards and practises; custom imitation, the imitation of the past; and rational imitation, the imitation of that which is logical and reasonable. These sociologists did not deal with the psychological mechanisms behind imitation but assumed that man possessed a propensity or inherent tendency to imitate.

J. Mark Baldwin attempted to bridge the gap between individual and social behavior by the concept of imitation. For him imitation became not only the mechanism of individual learning but also the basis of social organization. He conceived of imitation as a basic process by which the personality is built up within the social matrix of group life—first by the imitation of the external world of persons and then by self-imitation, which is important in the rise of social self-consciousness—and also as the “method of social organization” through the dialectic of social interaction.

Students of animal and human behavior have used the concept of imitation to explain the mechanics of learning. The psychological literature on imitation among men and among the lower animals is in a state of confusion, to which a failure to agree on terms has contributed. The existence of a definite innate basis or instinct of imitation as defended by McDougall and others is now doubtful. Imitation is rather to be regarded as a particular form of conditioning explained by the fact that the response of another becomes the conditioned stimulus for one's own response to the stimulus. So-called motor imitation among infants is perhaps a result of accidental association of like stimulus and response. Deliberate and rational imitation occurs only when the individual comes to possess free mental imagery and the related mental powers. Such behavior as yawning when others yawn or running in the direction in which others run illustrates what Bernard calls “automatic or suggestion imitation,” wherein a response becomes through long conditioning an unconscious stimulus for another person to perform a similar or identical act. Accidental or fortuitous imitation occurs in the behavior of children, when a chance com-

bination of stimulating circumstances sets up a chain of simple imitative responses which in turn become conditioned and integrated into the child's repertoire of habits and attitudes. Purposeful trial and error imitation, where one's action serves as the clue to another's similar or identical action, arises, as Mead has shown, only where there exists some motivation to perform the like action. The highest levels of imitation are those where rational or deliberate purpose comes into play and where projective or what Baldwin called “ejective” patterns within the individual serve as the basis for a reconstruction of one's internal, symbolic and meaningful ideas and attitudes. The concept of imitation, although in some disrepute because of its earlier connection with instinct psychology, thus remains a useful concept verifiable by experimental studies of animal and human behavior.

IMMIGRATION is the entrance into an alien country of persons intending to take part in the life of that country and to make it their more or less permanent residence. European immigration into distant lands has been part of the economic and social structure of the western world since the modern colonizing movement, which started in the sixteenth century. It was the means by which European culture was spread to the undeveloped regions of the world and since the development of these regions into independent nations or dominions it has served to redistribute population between the old, congested,

and the new, sparsely settled, countries. There was virtually no intercontinental immigration from the Far East before the nineteenth century, except for sporadic population movements in the fifteenth and seventeenth centuries. Both in volume and in the intensity of the problems produced by the entrance of alien peoples into a different land, immigration assumed its greatest importance in the nineteenth and twentieth centuries; many of the conditions characteristic of the later movement were present, however, in the colonial settlements.

Whenever areas of greater and less advantage lie within access of each other and governmental regulation does not intervene, migration toward the more favored spots will tend to take place both within a single country and internationally. In their economic aspects international and intranational movements differ little. The position on the western American frontier of the migrant from the eastern seaboard was often similar to that of his neighbor who had come from overseas. Likewise those who left the farms to seek their fortunes in industrial and urban centers within their own country frequently had to make much the same economic adjustments as peasant immigrants entering the same factories. The difficulties of cultural adjustment are, however, greatly augmented for the immigrant by the distance traveled, the change in his political status and the cultural differences of the new environment. Where close proximity, similarity of cultural conditions and international harmony prevail, as between the United States and Canada, immigration has practically the same characteristics as internal migration.

The direction of immigrant flow is determined by the lure of opportunity, real or imagined. Although enslavement or forced immigration has many of the same results as immigration, the latter movement is essentially a voluntary one involving active planning and conscious choice on the part of the immigrant. This quality of choice sets him apart from the majority of his countrymen, who accept the conditions of their homeland. Whereas emigration usually results from some sort of maladjustment produced by unfavorable home conditions, the direction of immigration is determined by expectation and the receiving country is affected by the immigrant psychology of hope and confidence.

The type of opportunity most generally sought is economic; the number of immigrants actuated by other than economic motives is proportionately small. The immigrant receiving countries

are therefore those offering richest economic opportunities in agricultural or industrial activity.

The effectiveness of economic advantage in drawing immigration depends upon the factors which facilitate or obstruct the process of transfer from one country to another. Primary among these is the ease of travel, a condition especially important in oversea settlement. The sharp rise in the volume of immigration in the later decades of the nineteenth century reflects the promptness with which migration responds to improved transportation. While travel affects the volume, conditions facilitating adjustment in the new country influence the direction of immigration. Similarity of culture and even more the presence of countrymen, friends or relatives draw immigrants to particular localities. Political and religious liberties attract refugees from persecution. Experience in a specific occupation and occupational bias exert a directive influence; Welsh miners, for example, have found their way to the mines of Pennsylvania and Swedish woodworkers have gravitated toward the furniture factories of the American middle west. The bulk of immigrants, however, have not been artisans or industrial workers. Although defective reporting makes the statistics on the occupations of immigrants too rough to permit accurate generalization, it is clear that the overwhelming body of immigrants have been agricultural workers, general laborers and domestic servants, most of whom have been drawn from rural regions. Their immigration therefore especially in recent years represents a drift from agriculture into industry, a shift which has seldom been reversed.

Immigration is sensitive to variations in economic advantage as reflected in the business cycle. When the industry of a country is in a depressed condition, immigration is checked, while at the same time emigration is stimulated. This effect showed itself conspicuously in Argentina beginning in 1914 when poor business conditions and extensive unemployment not only reduced the volume of immigrants greatly but actually reversed the direction of flow, so that the country became an emigrant sending instead of an immigrant receiving country. The same shift has occurred in the United States where the depressions of 1907, 1921 and that beginning in 1929 have each produced an excess of emigrants over immigrants.

Most immigration is a collective drift rather than a movement of an integrated mass. Although sometimes almost a whole village migrates piecemeal to another country, the general movement

is highly individualistic, for the immigrant is drawn from among the ambitious who seek personal advancement and the misfits who seek escape. The character of particular immigrations is determined by the circumstances producing emigration rather than the conditions attracting immigrants. Where a minority group has a particularly unfavorable status in the country of egress, those who immigrate may represent a cross section of that group; this has been conspicuously true of Jewish and Armenian immigration. On the other hand, Italian immigration, which has constituted the largest single element in the European immigrant stream of the twentieth century, has been far from a representative cross section of the Italian community, for it has been drawn overwhelmingly from low economic levels. The conditions forcing egress also determine in a large measure the age and sex composition of the group and its rate of permanence or repatriation. Since Italian immigration was almost wholly economic in motivation and did not represent a desire for change of habitat it contained a preponderance of males, and the proportion repatriated from 1902 to 1924 amounted to 62.8 percent of those going out. Among the Irish the sexes were almost evenly distributed, the female immigrants being drawn by the opportunities for domestic service; the Irish rate of repatriation from the United States between 1908 and 1923 amounted to only 11 percent, while the returning Jews have been estimated at 5 percent.

The nature of the impact of immigration upon the country of ingress depends upon the economic and social development of that country and the degree of similarity between the immigrants and the native group in economic equipment, living standards and cultural characteristics. These problems of social adaptation and of cultural transfer constitute the chief human issues involved in immigration. Although immigration of workers drawn from industry is replacing immigration from land to shop to an ever greater extent and although immigration for agricultural settlement still persists in South America, Australia and Canada, the history of modern immigration has been that of the increasing dominance of the land to industry type with the single outstanding exception of the Jewish group. This trend has complicated the problem of cultural transfer, for adaptation is more difficult under urban than under rural conditions. Although settlers are frequently on the move for new land to exploit, their act of immigration is a

commitment to a new place and way of life from which they do not look to return. The factory worker by contrast has a much smaller stake in his job, his life is much less dependent upon permanence than is that of the rural settler and his movements respond with great sensitiveness to conditions of the labor market. Although the life of the frontier is sufficiently different from that of the settled Old World village to dislocate most of the economic as well as the social habits of the settler, sometimes with disastrous results, the agricultural immigrant tends to gravitate toward a climate, if not a soil, which is familiar to him. Scandinavians in northern United States, Slavs in Canada and Italians in South America and California have all selected situations comparable to those to which they were accustomed. Rural adjustments involve principally the bare struggle for existence. But with the transfer of a peasant people to foreign industrial centers the usual strains set up by industrialization are increased by the pressure of alien speech and alien mores which bears more immediately upon them. In rural regions the traditional language can easily be maintained and the inherited customs can remain largely undisturbed. The city immigrant, however, is brought into close and active contact with the alien cultures of the country of ingress and with those of immigrants from other countries. Under conditions of individualistic agriculture the opportunities to exploit the settler's ignorance of the local ways and conditions are few. In industrial centers the immigrant is peculiarly subject to exploitation and is often unwittingly the tool by which the employer of native labor seeks to lower the standards of that labor. The disparity between conditions in the old and the new environment, differences in both real wages and money wages as well as the different position which money occupies in an industrial as against a rural community, all make wages below those which the native element demands appear generous to the inexperienced foreigner. Similarly, bad working conditions fought by native labor are accepted by the newcomer because they compare favorably with those to which he has been accustomed. As a foil for labor organization the foreigner is useful to the native exploiter or employer. Labor organization is checked by mixing nationalities to prevent communication, by pitting immigrant groups against one another, by playing upon Old World antipathies and by using immigrants as strike breakers. The most extreme forms of exploitation often come through the im-

migrant's own countrymen who have immigrated at an earlier date and who as padroni, foremen, saloon keepers or "boarding bosses" often impose upon the newcomers in ways the native employer would not know.

The least desirable jobs are assigned to the immigrant, and because these are performed by immigrants they are regarded as "foreigners' work" and native labor refuses to engage in them unless no other jobs are available. In the United States supporters of free immigration argued because of this that the nation's disagreeable work would not get done if the supply of willing immigrants were cut off. Immigration tends to delay the process of mechanization of industry by keeping a human supply cheaper than the cost of mechanical development. It militates against labor organization by introducing a wide breach into the ranks of labor, by permitting an aristocratic labor group to develop and organize for its own interest without considering the interests of the unskilled and inarticulate immigrants. The aspirations of immigrants for higher positions within the ranks of labor weaken class solidarity and labor organization. The fluidity of labor in a country which continually receives immigrants eliminates a more or less fixed set of labor relationships, which is one of the conditions most necessary to a substantial labor movement. Immigration is normally attracted to places where there is a labor shortage, and for this reason immigrant labor is usually welcomed by employers. Whenever there is or threatens to be an excess labor supply either in a single trade or in general, conflict between immigrant and native groups ensues. The immigrant is in an especially weak position in times of crises; in the United States he has been made the scapegoat for them since 1830. The powers of deportation were invoked and unemployed immigrants deported as public charges during the crisis following 1929. Labor organizations have fought consistently and vigorously for immigration restriction, for the exclusion of coolie and contract labor and for the general limiting provisions on immigration which were acquiesced in by the employing class only when the advantages of cheap labor with no fixed traditions became slight.

The social status of the immigrant results from the combination of cultural differences and economic status. His isolation from the life of the community which he enters is based on his low economic position, which in turn becomes associated in the minds of the natives with the nationality to which he belongs or with foreigners

as a class, so that the representatives of that nationality are assumed to be of low class and therefore socially undesirable. The social atmosphere surrounding the immigrant is thus surcharged with prejudice associated with his economic condition. The poverty of the bulk of an immigrant group in fact distinguishes the immigrant completely from other members of his nationality, so that any sympathy which may be felt for his fellow countrymen on their native soil is not extended to him. The problem of the transfer of immigrant cultures varies with the degree of divergence between the incoming and the native group. English speaking countries have regarded oriental immigrants as so diverse that no cultural amalgamation can take place, and orientals have consequently been virtually excluded from Anglicized regions. The shift in the source of most European immigrants from northern and western to southern and eastern Europe toward the close of the nineteenth century accentuated for the British dominions and the United States the problems involved in the transfer of immigrant cultures.

However similar or divergent its culture from that of the country of ingress, the immigrant group has the choice of sloughing off as rapidly as possible its traditional culture or rallying to its defense, clinging firmly and fervently to it. These alternatives are present whether the country of ingress is wild or settled, whether the immigrant faces the physical wilderness or the wilderness of an alien culture. The contrast is clearly displayed on the early American frontiers of Virginia and New England. In the former each man fended for himself as he entered the back country; he donned the moccasin and wielded the tomahawk of the Indian and sought to meet the conditions of the environment without regard for Old World traditions. In the latter the town group clung together, established its church and school and organized a closely knit community life around its cultural institutions. The strictness of the Puritan discipline, the merciless criticism and intolerance of social divergence, were a resultant of the group's response to the wilderness. The New England towns as outposts of civilization answered the challenge which the wilderness offered to their culture—its validity, applicability and power to survive—by standing in battle array organized and prepared to defend it. The immigrant colony in the heart of a city which maintains its own group life and builds up its own cultural institutions is meeting a comparable situation in a similar way.

Complete cultural adaptation of the immigrant is scarcely possible, for the tradition and education of every people rest largely upon an age long development and are so gauged to a particular place and the conditions of a particular social group that they are not appropriate to a new environment. The adult newcomer cannot therefore enter fully into an understanding and appreciation of native culture and achieves essential similarity with the native only in the most elementary or superficial terms. The vaunted democracy and individualism of the American frontier resulted from the fact that culture was there reduced to its simplest form. Social barriers were few because cultural inheritance had been discarded. On the social frontier of the industrial center the same process of cultural stripping has further added to the poverty of the national culture of the United States and to its emphasis on wealth and physical prowess as cultural measures of value. In the physical wilderness the choice lies largely with each group to maintain or to discard its cultural tradition and its group separateness. In an industrial city, however, the immigrant's choice is more frequently forced by both official policies and unofficial external pressures as well as by the nature of the native social organization. In the United States the nearly universal use of English for official, business and educational purposes, the public school system and the lack of recognition of cultural differences have exerted a strong positive pressure to make the immigrant drop his own culture. Canada and most South American states are in contrast multilingual and education varies with each cultural group.

Neither the process of establishing ethnic communities nor that of cultural assimilation solves the problem of cultural transfer. The one perpetuates the alienism of the immigrant group; the other involves a wastage of human values in not utilizing the accumulated experience of the past. In either case personal maladjustment on the part of the immigrant generally ensues and either the cultural poverty or the cultural confusion of the immigrant receiving country is inevitable. This result is inherent in the nature of the immigration process. The individual immigrant registers his protest against his tradition by his act of departure. Every immigrant group is thus antitraditional in its social philosophy and individualistic in its values. People without a cultural home, like the Jews, are exceptional; they have had to build their traditions on all soils and do not move to repu-

diate their own group but rather that among which they find themselves. The incompatibility of the culture which the immigrant brings with the new environmental conditions results in a still further reduction of the traditional element in his social custom and point of view. Only where the conditions of individualistic, equalitarian assimilation have not prevailed has there been a cultural development beyond elementary bounds. It was the Puritan group with its technique of group resistance in meeting new situations which transmitted a cultural tradition to the United States; it is those who, like the Jews, have not come to escape from their own cultural tradition or who, like the Negroes, have been forced into cultural isolation that have developed distinctive cultural and social patterns which can enrich and embellish American cultural life. Every city immigrant group organizes its colony or ghetto with its characteristic food stores, its mutual benefit societies, newspapers, steamship agents and banks for handling remittances to the home country. To the extent to which these colonies retain the flavor of the Old World they are to the immigrant home. Their colorful, teeming life lends a picturesqueness to otherwise drab cities; but they have in the United States no status as quarters—they are a part of the slums, which their leaders leave as soon as they achieve a measure of individual success.

Since the immigrant can neither slough off completely the results of his home education nor capture the inwardness of his new environment however much he seeks to do so, he is bound to impart to his children some measure of his traditional social pattern. The children, who are exposed in the United States to an environment which expects from them complete conformity and a repudiation of alien ways, are torn and confused by the conflict. With the often unwitting sanction of the educational institutions in which they are enrolled they repudiate parental direction. Their alien home environment and their lack of close contact with native persons make their problem of adaptation difficult. The presence of many American born children of immigrant parents in the ranks of gangs must be attributed to the failure of America to recognize the complexity of the culture pattern of even the simplest people and to provide the means for the cultural adjustment which must follow immigration. The problem of immigrant adjustment is most acute in the second generation, but even four generations have not, in the case of the Irish and Germans, for example, served to

eradicate differences. The problem of the development of a national culture out of immigrant peoples is the problem of the level at which assimilation shall take place. Individualism has resulted in draining off from immigrant groups their more educated or abler members and their incorporation into the cosmopolitan American group. It has made no impression, however, upon the masses, which remain either disorganized or in nucleated, unassimilated cultural groups. No immigrant receiving country made up of a diversity of immigrant peoples has as yet successfully solved the problem of mass amalgamation.

Before the nineteenth century the immigration policy of the colonizing powers was governed by the demands of mercantilism. With the exception of the English colonies immigrants were selected largely on the basis of nationality and religion and an attempt was made to exclude paupers and convicts. Eager for numbers most North American colonies offered inducements to those who persuaded others to cross the seas. In the latter part of the seventeenth century the English government in spite of the protests of the colonists began to unload its undesirables upon its continental colonies, which it did not regard as very important. After the American Revolution it transported convicts to Australia and its paupers usually to Canada. Spain rigidly restricted immigration into her colonies; but after the Hispanic American countries achieved independence they reversed the policy of their parent countries by including the right of immigration in their constitutions and laws as a fundamental principle. After the United States became a nation it was regarded as the land of the free, the haven for the oppressed subjects of political tyranny and the land of opportunity for the poor and destitute of the world who were willing to labor. The wealth of natural resources, which was expected to remain unexploited for many centuries, made unlimited labor welcome. Doubts of the unconditional value of immigration were based primarily on political rather than on economic fears. Except for the hysteria surrounding the passage of the Alien and Sedition Acts of 1798 these doubts were slight—so slight in fact that aliens who declared their intention to become citizens were accorded the vote in frontier western communities. At no time, however, did the federal government of the United States adopt a policy such as that pursued in the British dominions and the South American countries of officially soliciting and assisting immigration. With the rapid increase of immigration into the

United States between 1830 and 1840 opposition to immigrants began to be manifested. Massachusetts and New York complained of the alien paupers who were filling their almshouses and sought to assess head taxes on entry or to require the masters of vessels to give surety for their passengers, but these measures were declared unconstitutional as invasions of the realm of interstate and foreign commerce. Labor writers in the 1830's who called for protection against the importation of foreign labor comparable to the tariff on the manufacturer's product reached a much more limited audience than did those who decried immigration as a "foreign conspiracy against the liberties of the United States." Immigration appeared as an impending danger to American political institutions, the opponents warning especially against those who, they declared, owed allegiance to the Roman pontiff. The protest gathered political force and culminated in the organization and subsequent victory at many local polls of the Know-Nothings, or American party. Native American agitation, however, did not lead to restrictive legislation, partly because the Civil War intervened.

The first federal restrictive measures on immigration in the United States were directed against Chinese coolies; American vessels were forbidden to transport them in 1862 and they were excluded from entry in 1882. In singling out the Chinese for exclusion the United States joined a movement which was becoming general among Europeanized countries, on the grounds that diversities in race and culture and the extremely low standard of living of the vast masses of potential Chinese immigrants were a menace. Canada followed the American exclusion act with a restrictive measure in 1885 in the form of a special head tax. Australia after the passage of regulatory acts by the several colonies and after a bitter fight over the principle of whether the country should remain white made exclusion virtually complete by the Commonwealth Immigration Restriction Act of 1901, which empowered officials to require immigrants to pass a dictation test in any specified language.

American restrictive acts were not directed against any specific race or nationality other than the Chinese until after the World War. They were instead designed to exclude undesirable individual immigrants. Convicts and prostitutes were first banned in 1875; "lunatics," mental defectives and persons likely to become public charges were excluded in 1882. At the instigation

of organized labor contract laborers were denied entry in 1885. In 1891 certain diseases were made the basis of exclusion, as was polygamy. In 1903 the first abandonment of the policy of maintaining a refuge for the politically oppressed came with the exclusion of anarchists. A literacy test for immigrants was vigorously contested but finally passed in 1917 over a series of presidential vetoes. The act of that year, the basic regulation upon which numerical and national restrictions have been superimposed, extended earlier measures and sought to provide for the protection of the United States politically through the imposition of a literacy test and the elimination of anarchists and advocates of violent revolution; physically through the exclusion of persons carrying dangerous diseases; morally through the exclusion of those guilty of "moral turpitude"; and economically through the exclusion of those likely to become public charges. The World War broke down completely the traditional policy of a free America. The revelation of "hyphenated Americanism" combined with the doubtfully reliable but much publicized results of the physical and mental tests made upon soldiers drawn from various immigrant groups released the forces of opposition to the new non-"Nordic" immigration which had been gaining strength since 1882. The wholesale exodus from stricken European countries at the close of the World War dissipated the last shreds of effective resistance, and a quota law with its limiting of volume and its selection on the basis of nationality was enacted in 1921. These restrictions, which discriminated against immigration from southern and eastern Europe, were increased in 1924. The law with its "national origins" provision effective in 1927 limits the quota immigrants to 150,000 a year and favors immigration from Great Britain as against other "Nordic" groups.

The quota system had its roots in the diversity in the degree of adjustment of different immigrant groups, for whereas the abandonment of a laissez faire attitude toward immigration in favor of limitation came in response to changed economic conditions, the form which restriction took was completely non-economic. Although it marked a departure from the traditional open shore attitude it retained and reenacted in the light of earlier experience and modern conditions the old principle that the basis of immigrant adjustment should be the sloughing off rather than the reenforcing of alien cultures. The war-time experience clearly revealed the presence of

national groups which had failed to follow this prescription. At the same time with the passing of frontier conditions the increased sophistication of American culture made the problems of assimilation more complex. No longer was culture reduced to the simple terms of wealth, physical strength and the free democratic institutions that the native American party had cherished nor to the Protestant faith for the defense of which the American Protective Association had been organized in 1887. Discerning more subtle cultural values but without faith in the possibility of the amalgamation of alien cultures with the American cultural pattern and fearful lest control should pass to an alien cultural group, the dominant groups in America fostered a belief in "Nordic" superiority and then pressed successfully for restriction on a cultural rather than an economic basis.

Most of the features of the United States laws except the quota law are to be found in the regulations of other countries, but the latter have not gone so far as those of the United States either in national selection or in absolute numerical limitation. Orientals are generally excluded except from the majority of South American countries; convicts, prostitutes, the mentally and physically infirm and the advocates of violent revolution or anarchy are almost universally banned. Canada, Australia, South Africa and Mexico also may require immigrants to be literate, but the South American countries do not. Canada has gone further than other countries in seeking to adapt its immigrants to economic conditions; it requires that the immigrant possess a considerable sum of money when landing, maintains an employment service in direct contact with the Ministry of Labour in London, which calls for the type of labor needed in the dominion, and authorizes the governor general to issue orders in council regulating immigration on economic grounds. Both Australia and Brazil empower appropriate administrative officials to prohibit or suspend immigration on economic grounds.

Control over immigration has been exercised by all immigrant receiving countries as a matter of internal policy wherever the exclusion of individual undesirables has been involved. Where it has been directed against the nationals of a particular state it has led to international friction. Chinese exclusion from the United States was preceded by a treaty with China establishing the right of the United States to suspend immigration from that country. Japanese laborers were largely prevented by "gentlemen's agreements"

from entering the United States and Canada, until the United States over the protests of the Japanese diplomatic representatives transformed the international agreement into domestic legislation by the Immigration Act of 1924 excluding aliens ineligible for citizenship. The American quota system, the designation of "preferred" nationalities by Canada and the Australian provisions for admission on the grounds of assimilability have all been entered into without consultation with or regard for the interests of immigrant sending countries. The latter, especially Italy, have retaliated with limitations on the right of emigration. Friction has become particularly acute where the proportion of repatriations is large and the immigrant sending country has sought to keep control over its nationals abroad in the expectation that many of them will return. The policy of Italy in this respect has been a source of irritation to the United States. Faulty administration of restrictive acts resulting in the return of incoming immigrants from the ports of entry has added to the hardships of restriction and to international ill will. To remedy this situation entering immigrants are now required by most countries to secure visas, and the responsibility for selecting admissible immigrants is placed in the hands of consular representatives in countries of emigration. Within the British Empire the right of the present dominions to restrict immigration from the mother country was only gradually established, and much ill feeling has been generated by the question of Indian immigration. In an effort to promote the international regulation of migration with mutual understanding among nations international conferences on migration have been held since the World War and the International Labour Office has made itself responsible for the collection and publication of information regarding population movements and regulations existing within and among countries.

The effect of the considerable body of restrictive and regulatory legislation since the World War has been to change the character of immigration from a haphazard movement to a carefully regulated one, severely to cut down its volume and largely to deflect the direction of its flow. As immigration in the seventeenth century broke up the excessive rigidity of the mediaeval economic and social organization, its restriction in the twentieth may be regarded as an effort to redress the balance against excessive fluidity and absence of direction. As a result the differences

in the standard of living and population density between new and old countries are being perpetuated. The countries of Europe and Asia, suffering from density of population, are being forced to find some solution other than emigration for their maladjusted nationals. Within the British Empire a solution for the needs of both England and the dominions was attempted by the Empire Settlement Act of 1922, which provided for assisted emigration of British nationals to the dominions under both British and dominion auspices. Emigrants from England, however, frequently cannot meet the requirements chiefly of an economic character imposed by the dominions, such as the requirement that immigrants shall be farmers or that they shall have sufficient capital to set themselves up on the land or in business. European immigration to the United States has been reduced to a small fraction of its pre-World War volume. But as the quota provisions do not apply to Mexico, Canada, Porto Rico and the Philippine Islands—the latter two not subject to restriction because they are dependencies of the United States—these countries are now the principal sources of cheap immigrant labor. In this way the objects of the quota law are defeated, for the racial disparity between the old American and the Mexican, Porto Rican and Filipino stocks is greater than that between Americans and European immigrants. Brazil and Argentina remain eager for population expansion with few restrictions and with favorable provisions for the recruiting and settlement of immigrants.

IMMUNITY, DIPLOMATIC. Heralds and envoys have been employed for international intercourse from the very beginning of politically organized communities. The ancient states of Asia had established ceremonies and formalities accompanying the interchange of embassies. In Greece and Rome diplomatic intercourse attained a high degree of development and immunities enjoyed by envoys were well established. It should be noted that the right of legation active and passive, that is, the right to send and the correlative duty to receive envoys, was fully recognized. Up to about the thirteenth century envoys were sent largely for the performance of particular, isolated tasks, such as the negotiation of a truce or of a treaty. Thus their mission was chiefly political. It was necessary to insure their inviolability; since law and religion were scarcely distinguishable and the highest law was at this early period divine law, the person of the envoy—who frequently was a priest—was regarded as sacred. Diplomatic immunity throughout this

early period was supported more by religious than by legal conceptions. With the appearance of centralized states and the development of international commerce the intercourse of states became more intense and more continuous and led ultimately to the establishment of resident embassies. From merely political the task of the envoys became also to a certain extent economic and consisted chiefly in supplying information. On the political side jealous rivalry, conflicting ambitions, territorial or otherwise, and the intermingling of dynastic with national interests impelled the monarchs to watch through their envoys events in other countries. On the economic side they were interested in the possibility of assuring expansion or of safeguarding interests already acquired.

From the end of the thirteenth up to almost the end of the nineteenth century envoys were regarded primarily as the personal representatives of the monarch, in whom the state's sovereignty was embodied. The immunities enjoyed by these representatives were considered therefore as due to them on account of the dignity of the prince they represented. A legal basis for these immunities was found in the fiction of extraterritoriality. According to this fiction the envoy of a foreign sovereign was not in legal contemplation within the territory of the receiving state and his dwelling was part of the territory of the state which sent him. Therefore he and his residence were not subject to the operation of the local law. The immunity of the residence was for a time carried to such an extent that not only the house but also the whole quarter wherein a foreign mission was located was regarded as extraterritorial. The rationalizing tendency in modern international law gave, however, a serious blow to this fiction. Sovereignty passed in most countries from personal monarchs to the people, and the envoy today represents the state rather than the person who for the time being is the head of the state. His task now is to represent generally and to protect the interests of his state and its citizens, whether these interests be political, economic or of any other character. Friendly relations between nations require that he should in no way be hampered in the performance of his functions and that respect and protection should accordingly be afforded to him. To accomplish this object it is unnecessary to resort to a fiction which is factually untrue and legally unnecessary.

Diplomatic immunities consist of (1) the inviolability of the person of the diplomatic

representative; (2) his exemption from local jurisdiction whether civil or criminal; (3) exemption from taxation; (4) immunity of the mission's offices and the residence of the diplomatic representative; (5) freedom of correspondence and communications. The early insistence on freedom of religious worship is no longer important because that freedom is no longer called in question. These immunities are extended not only to the chief of a mission but also to the staff (counselors, secretaries, attachés), to their families and very generally to all employees of a mission provided that they are not nationals of the state to which the mission is accredited. It has not yet been clearly determined to what degree of family relationship this immunity of employees and subordinate members of a mission extends. Where the employees are nationals of the receiving state there is a difference of opinion as to whether such persons enjoy any immunities at all or whether they enjoy immunities only with respect to acts performed within the scope of their employment.

The classification of chiefs of missions by the Congress of Vienna in 1815 and by the Congress of Aix-la-Chapelle in 1818 (ambassadors, envoys, ministers resident and *chargés d'affaires*) was undertaken with a view to putting an end to irritating disputes over precedence and other questions of etiquette and is immaterial in the substantive law as to the extent and nature of immunities.

Diplomatic immunities are almost exclusively the creation of customary international law. There are relatively few national legislative acts defining the substance and extent of these immunities. When cases come before courts the issue is usually determined with a reference to "the generally accepted principles of international law." Great Britain, however, in order to placate the outraged czar after the arrest of the Russian ambassador enacted the Diplomatic Privileges Act of 1708 (7 Anne, c. 12), which forbids the issuance of a writ or process against any foreign ambassador, his "domestic or domestic servant." This act, held subsequently to be merely declaratory of the law of nations, was substantially reenacted in the United States by the Act of Congress of April 30, 1790 (U. S. Rev. Stat. sects. 4062-66). Germany has also provided for the exemption of diplomatic agents from local jurisdiction (*Gerichtsverfassungsgesetz* (1877, sects. 18-20). A considerable number of countries provide by statute for the punishment of persons offending the person of a foreign diplo-

matic representative. A few treaties concluded with Asiatic powers and recent treaties concluded with Soviet Russia have undertaken to provide for and to define the extent of the immunities to be accorded to the diplomatic representatives of the contracting parties. On the other hand, laws can be found in most countries concerning the exemption from taxation of the person, income and property of diplomatic representatives. It is a controverted question whether exemption from taxation is a matter of right, as is exemption from the jurisdiction of the courts, or whether it is a matter of courtesy or international comity. The fact that in the majority of cases—especially in relation to customs duties—such exemption is conditioned upon reciprocity seems to support the latter view.

As a matter of courtesy rather than of strict right certain immunities are granted to diplomatic representatives while in transit through other states to or from their post.

Diplomatic immunities are usually extended to ad hoc representatives of states, such as, for example, delegates to international conferences, members of international tribunals. Indeed the problem of immunities was considerably complicated by the establishment of the League of Nations, of which the permanent staff as well as the delegates to the meetings of various organs enjoy diplomatic immunities while on such missions (art. 7, sect. 4 of the Covenant of the League of Nations). In view of the increasing number of the staff of the Secretariat the recent tendency to restrict diplomatic immunities in general has manifested itself with particular emphasis in respect to League officials and officials of other international organizations. The complication that has arisen in respect to representatives of Soviet Russia has been due not only to certain political considerations but to the extended commercial activity of a nationalized industry and commerce carried on abroad through numerous diplomatic agents, to whom the western states have found it undesirable to accord these immunities without restricting the number of persons who are entitled to them or without defining the extent to which these immunities shall go.

It seems in general that the whole issue of diplomatic immunities is in the process of clarification and rationalization. The tendency is doubtless toward a restriction of immunities which have been perhaps accorded to a greater extent than the unhindered performance of a diplomatic representative's duties necessitated.

This tendency is manifested in discussions by text writers and is followed with increasing frequency by courts in continental Europe in confining the immunity merely to acts performed by the diplomatic representative in his official capacity, excluding acts which have no relation to his character as a diplomat, such as acts connected with a business conducted privately. The League of Nations Committee of Experts for the Progressive Codification of International Law included diplomatic immunities in the list of subjects which it held ripe for codification, but this subject was not included on the agenda of the First Codification Conference held at The Hague in March, 1930. It is possible, however, that in the near future the law applicable to this question will be embodied in a multipartite convention. The Institut de Droit International suggested as early as 1891 and revised in 1929 a draft convention relating to this subject. At the conference of American states in Havana in 1928 a convention applicable to the relation of American republics was signed. The most carefully prepared suggestion for codification has been that made by the Harvard Research in International Law and published in the supplement to the *American Journal of International Law* (vol. xxvi, 1932).

Good bibliographies of the exceedingly voluminous literature on diplomatic immunity are to be found in Hershey, A. S., *The Essentials of International Public Law and Organization* (rev. ed. New York 1929) ch. xviii.

IMMUNITY, POLITICAL. Legislative bodies are among the agencies by which expression may be given to the needs of the various groups constituting the state. In the public interest safeguards must be designed to insure the full independence and functional freedom of these bodies. Political immunity implies that legislatures have an inherent right to protect their

dignity and that members must be exempt from arrest or molestations which might interfere with the exercise of their public functions. Freedom of speech for legislators is essential to insure criticism of public policies without fear of punishment or discipline.

The theory of political immunity can be traced to the early history of the English Parliament, a body which originally had both judicial and legislative functions. Underlying Parliament's claims of privilege from earliest centuries to modern times was the conception of Parliament as the highest court of the realm, entitled to peculiar protection and dignity and transcendent in its jurisdiction. Whatever the political exigencies of Parliament as a supreme legislature in Tudor and Stuart times, it defended its claims to immunity on the theory that it acted in its old judicial capacity in matters of privilege. Its members enjoyed special protection from arrest, interference and molestation of every kind and were free from the orders of other courts. Interferences with the freedom and safety of members or with the dignity of Parliament were prevented by the right to commit offenders and hold them in contempt.

Although there are earlier cases, controversies over privilege between Parliament and king, the law courts and individual subjects became numerous and important only after 1640 when Parliament became more active as a legislative body. Parliament's new legislative supremacy was frequently defended by appeals to its traditionally recognized judicial supremacy. Parliament in claims of immunity acted under the special *lex et consuetudo parliamenti*, regarded for centuries as above the law of the land. No abuse of Parliament's privileges could be examined in the ordinary courts because the law of privilege was an exception to the common law. Judges who took a different view encountered the punitive powers of a parliament house. Privilege was the last of the mediaeval liberties to be reduced by common law. The inevitable result of this conception of parliamentary privilege was a long conflict between courts and Parliament. During the Stuart period the issue between royal prerogative and the growing legislative powers of Parliament became acute since both privilege and prerogative claimed to be exempt from the ordinary course of the law. Interference on the part of the inferior courts was bitterly contested by the House of Commons as long as the whole membership of the House of Lords, by virtue of its position as the supreme

appellate court of the realm, was enabled to pass upon the political immunities of the lower House.

Parliamentary privilege, which under the Stuarts had been a weapon against arbitrary despotism, later became itself a serious menace to the liberty of the subject. For three quarters of a century after 1688 the House of Commons exercised as great an independence of popular rights and as great an irresponsibility toward them as had the Stuart kings. The reporting of debates was punished as a breach of privilege or was permitted as a vehicle of slander against individuals; petitioners were treated as criminals and disputed elections were decided by mere party votes. Under the guise of privilege exceptions were made to the law of the land. Ordinary cases of trespass and petty thefts—breaking a fence or stealing timber on a member's land or catching fish in his pond—were punished not by the ordinary courts but as breaches of privilege. "Protections" were issued to members' servants and others who had no connection with either House, and under this abusive form of parliamentary indulgence the offender was removed from the jurisdiction of the law courts and under the *lex parliamenti* the victim was left without a remedy.

From the fifteenth century through the nineteenth the conflicts over the extent and operation of privilege were fought out in cases involving assaults, libels and threats against members, bribery, tampering with parliamentary witnesses, freedom of speech, jurisdiction over election cases, freedom from arrest and molestation—which for a long time applied to members' property and servants—and in controversies over the duration of privilege, which Parliament never accurately defined but which always included the time of going to and returning from a session. The Bill of Rights of 1689 gave statutory recognition to immunity for debates and proceedings in Parliament and later statutes provided other delimitations of privilege. Many privileges still rest on the law and custom of Parliament. The houses of Parliament retain their powers to commit for violations of privilege, to compel the attendance of witnesses and to protect officers executing the orders of the House.

The precise jurisdiction of the courts of law in cases of privilege is an extremely complicated matter and precedents and decisions differ. Nevertheless, it may be said now that the *lex parliamenti* has become part of the all embracing, fundamental common law of England. Great constitutional changes like that in the appellate

jurisdiction of the Lords and in the democratization of the House of Commons made this solution easier to accept. Today practically any process that does not affect the person of a member or prevent his actual attendance in Parliament may be issued. Neither House can any longer create a privilege by mere resolution and courts may of necessity be compelled to pass upon the validity of the claim. Officers of Parliament may be exposed to the censure of the law should it develop that their orders were based on an unjustifiable interpretation of political immunity. There is no privilege at present which is not pleadable at law or examinable by the courts should it come before them in a judicial way. Moreover the claim of privilege has always been legally limited in England to civil causes. Cases of "treason, felony and breach of the peace" have always been excepted. Members of Parliament are never outside the law, although private interest must yield to public interest while the legislature is in session.

Procedure in the British dependencies and dominions naturally follows the precedents of the "mother of Parliaments"; but it has been repeatedly held by the courts and the British Privy Council that the privileges of assemblies must be justified by the strict rule of necessity and are not to be compared with those of Parliament, which acts by a peculiar law and in a judicial capacity. Colonial legislatures have never been clothed with those general powers of commitment and punishment enjoyed by the English Parliament. In the United States the federal constitution defines the privileges of Congress and makes each body the judge of its elections. Authoritative American opinion follows the theory that the power to punish contempts is an auxiliary power by which Congress is able to make its deliberations effective and which follows from the broad grant of power to legislate. Congress has no discretionary power to declare contempts but it has repeatedly punished offenders who molested members, refused to witness before committees or in other ways menaced the honor and dignity of the legislative body.

The English conception of political immunity spread to other countries with the introduction and growth of parliamentary government. At the time of the French Revolution fifty-two of the *cahiers* issued to the French estates for the elections prior to the outbreak of revolution demanded that representatives be inviolable and some included immunity during the continuance of the session for civil cases as well. Under the

lead of Mirabeau the National Assembly of 1789 by formal resolution introduced parliamentary immunity into France. Later constitutions restated the principle in various forms. In 1790 protection against molestation outside the walls of parliament was included in order to counteract the operation of *lettres de cachet*. The *loi constitutionnelle* of 1875 restated the privileges of the French parliament. Although the chambers make their own rules of procedure and enforce discipline upon their members they do not enjoy the broad power of commitment for contempt which the British Parliament possesses. Each chamber is the judge of the eligibility and election of its members and members enjoy the ordinary guaranties of freedom of speech. No member may be arrested on a criminal charge during the session without the authorization of the chamber to which he belongs. This immunity does not apply to petty offenses against police rules but only to cases *criminelles et correctionnelles*, and immunity ceases even during the session in *cas de flagrant délit*.

The French procedure of the early nineteenth century was incorporated in the Belgian constitution of 1831. The Swiss procedure is much the same although there are a great many minor differences in the various cantons, which follow both French and German precedents. The issue has had little practical importance in Switzerland and six cantons are able to dispense with any formal statement of immunities. Present day procedure in Italy, Greece, Spain, Japan and the South American countries follows in broad outlines the French model.

In Germany immunity for representatives was unknown in the seventeenth century and members of assemblies who offended their rulers by their actions and speeches were often wilfully punished. German publicists in early years were content in such cases to plead for a legal trial to supersede the arbitrary punishment of irritated rulers. As the ideas of the French Revolution penetrated Germany parliamentary immunity made its appearance in the Bavarian constitution of 1818 and in the Prussian constitution of 1850. English and French precedents were followed and although prosecution for speeches made in parliament was generally prohibited, exceptions continued to be made for insults to the royal person or family. The constitution for the unified empire of 1871 went back to French precedents and the demands of the liberal Frankfort Assembly of 1848.

The German republican constitution of 1919

provides that election disputes are to be settled by a committee of Reichstag members and a number of judges of the Reichsverwaltungsgericht holding public sessions. Full immunity is guaranteed at all times for votes and official utterances of all members of legislative bodies, federal and state, but this does not apply to private press interviews or speeches at conventions. No member may be arrested during the session for any punishable offense without the permission of the Reichstag, unless seized at the time the offense was committed or not later than the first day following. All illegal acts may be prosecuted but not during the session unless the Reichstag permits. Confidential information received by a member in his capacity as a representative is also completely privileged. Austria follows German and French precedents. The Yugoslav constitution of 1931, on the other hand, provides that members may be tried by ordinary courts, without the previous consent of the parliament houses, in case of injuries, calumnies and crimes.

IMPEACHMENT. An impeachment in the widest sense of the term is a criminal accusation brought in a legislative body. Although popularly used to embrace the proceeding in its entirety, the term does not in strictness include the verdict or the imposition of sentence.

Although impeachment is of course a modern

institution, the ancient Greek *ostracism* bore a close resemblance to it. A Greek citizen could be impeached before the political assembly in certain cases, and the method was frequently used when there was misconduct in public office.

Impeachment originated in England as an outgrowth of the plenary judicial functions of the Curia Regis. These functions passed to the House of Lords after the separation of Parliament into two houses. Developed as a means of enforcing the responsibility of the higher officers of the crown to Parliament, impeachment was undermined in the land of its birth by the introduction in 1700 of the removal of judges upon address of both houses of Parliament; soon after the beginning of the nineteenth century it was rendered practically obsolete by the development of the doctrine of ministerial responsibility. The impeachment of Warren Hastings brought the institution into discredit, and it was last used in the case of Lord Melville in 1806. Used sporadically in one or another of the colonies, it found place in the first constitutions adopted by Massachusetts, Virginia and South Carolina. Incorporated in the United States constitution, it has since become part of the constitution of every state except Oregon. In manifold variation of form it has been adopted also by a great many other nations, including France and several of the smaller European states, Mexico and South American countries generally. Known in many German states before 1919, the Weimar constitution introduced it into the national public law.

In England impeachment will in theory lie against all kinds of crimes and misdemeanors, even though wholly unrelated to the public service, and against offenders of all ranks. Historically after its earliest stages it has been reserved almost exclusively for high officers of state and for offenses in or relative to their office. Under the federal constitution impeachment is available against "the president, vice president and all civil officers of the United States" (art. II, sect. 4). That members of Congress are not "civil officers" within the meaning of this provision is the accepted view, although never unequivocally decided. In the state constitutions a wide variety of provisions is found, the usual effect being to include all state executive and judicial officers except minor judges. In France it is possible for any individual to be impeached before the Senate for a crime so grave that it endangers the safety of the state. The general tendency in most other European countries and in South America is to confine impeachment to

officers of ministerial rank but to extend it to all offenses against the constitution or laws.

In its development in England as a crude and cumbersome means of enforcing ministerial responsibility to Parliament impeachment of a minister for having been guilty of bad judgment (technically, giving bad advice to the king) was regarded as entirely proper. In the Constitution of the United States "treason, bribery, or other high crimes and misdemeanors" are the sole impeachable offenses. In the state constitutions in addition to these one finds not uncommonly such offenses as malfeasance, gross misconduct in office, negligence and corruption. Whether it is necessary that the offense be one indictable under a statute is unsettled; as to federal impeachments the best opinion is in the negative.

Whether misconduct of an officer in a private capacity, but of such a character as to indicate unfitness for office, is ground for impeachment in the United States depends primarily on the offenses declared impeachable by the constitution; so also as to misconduct prior to assuming office. Under the federal constitution neither point has been expressly decided but authority favors the affirmative on both. In New York in 1913 Governor William Sulzer was impeached and removed from office on two charges, one based on alleged acts prior to his assuming office. The importance of this case as a precedent is, however, greatly diminished by the fact that New York is one of the nine states in which the constitution specifies no ground for impeachment (Connecticut, Idaho, Georgia, Maryland, New York, North Carolina, South Carolina, Texas and Oregon).

In England, the United States, France and almost all South American countries the function of accusation is vested in the lower house of the legislature and the function of trial and sentence in the upper house. In New York the judges of the highest court of the state are added to the upper house. In Nebraska trial is by the courts upon charges preferred by a joint convention of both houses. In most European countries the collaboration of legislative and judicial branches in the impeachment process is also found in various forms. The trial takes place before some high court, such as the high court of state (as in Germany) or the court of cassation (as in Belgium) arrangements that bespeak a growing conviction that the trial of an impeachment should be as nearly as possible a judicial process. In the United States the usual requirement as to vote is that of the federal constitution—a major-

ity vote in the lower House (although seven states require a two-thirds vote) and a two-thirds vote in the upper house. This is not the case in the British House of Lords. Since ordinarily no separate findings of fact are made, a judgment of acquittal on a particular article of impeachment fails to dispose of the question of the legal sufficiency of such article.

The provision in the federal constitution that "Judgment in cases of impeachment shall not extend further than to removal from office, and disqualification to hold and enjoy any office of honor, trust or profit under the United States: but the party convicted shall nevertheless be liable and subject to indictment, trial, judgment and punishment, according to law" (art. 1, sect. 3, par. 7) is followed in substance in virtually all the state constitutions and represents the prevailing tendency in most countries. It represents a complete break with the English tradition, which recognized no limitations on the penalty which might be imposed, death and forfeiture of property being found among the penalties in historic cases. Whether such a provision precludes the impeachment of one no longer in office has apparently but not unmistakably been decided in the affirmative under the federal constitution. Most state constitutions are silent on the point, but those of Georgia, New Jersey and Vermont specifically include former officers.

The cumberdomeness of the machinery of impeachment under the federal and state constitutions and the tendency to restrict its application to cases in which the offense is very grievous and to draw the rules of evidence and proof from the criminal law have resulted in its relatively infrequent use. In all there have been impeachments of nine federal officers (six of them judges), of whom three were convicted. No complete list of state impeachments exists, but the total number doubtless does not much exceed one hundred. In addition to Governor Sulzer three other governors have been impeached: Ferguson of Texas in 1917, Walton of Oklahoma in 1923 and Johnston of Oklahoma in 1929. Although impeachment is susceptible of abuse for political ends and has undoubtedly been so used in a few cases in the United States, the extraordinary majority required for conviction ordinarily bars the possibility of such abuse.

IMPERIAL PREFERENCE. See COLONIAL ECONOMIC POLICY; COMMERCIAL TREATIES; TARIFF.

IMPERIAL UNITY. Empire has become so much associated in contemporary thought with imperialist conquest and coercion that it is easy to overlook the fact that an essential element of empire is cooperation and consent, based on unity—ethnic, economic and ethical, racial, regional and religious. This unity appears in its simplest expression in the earliest imperial concentrations of local communities under a central control; in more complex and cryptic forms it penetrates profoundly the structure of modern empires.

The earliest known civilizations, those of the Nile, Euphrates, Indus and Yangtze valleys, all reached the empire stage in much the same manner and at much the same epoch. In Egypt the nomes, or local communities, first concentrated into the national kingdoms of Upper and Lower Egypt; these two nations then federated into an ethnic empire as an economic entity although retaining their distinct character. A similar coalition occurred on the Euphrates between the kingdoms of Akkad and of Sumer, while on the Indus there was apparently a junction between the regional centers of Harappa and Mohenjo Daro. Thus the genesis of empire appears in voluntary association for the establishment of racial and regional unity. Religious unity came at a later stage as a result not of internal consensus but of conquest from outside by a simpler, less settled society. For whereas the valley civilizations under their diarchies of prince and priest had developed very diversified nature re-

ligions in connection with their diverging occupations as artisans and agriculturists, the more primitive pastoral tribes of the grassland borders between valley and forest had all alike adopted a uniform monotheistic sun worship. It was the conquest of urban and rural civilizations and of their nature idolators by these simpler pastoral puritans, of local deities by an abstract divinity, that gave the empires a new unity. In spite of the superficial union of the two Egyptian kingdoms under the god-emperor pharaohs there was no political peace until the conquest by the Hyksos about 1675 B.C. Until Sargon of Agade led northern sun worshipers to the conquest of the superior Sumerian civilization, there was no permanence of peace and progress in the economic entity that later became the Babylonian Empire. Similarly northern Aryans and Turanians seem to have unified the Dravidian civilization of the Indus and the civilization of the Chinese Yangtze. Thus did these earliest empires acquire the religious factor to complete the three essentials without which even today no empire can long endure. In later periods a new creed has either been adopted and adapted by an existing empire, as Christianity by the Roman Empire, or has asserted by arms an imperial unity of its own, as in the establishment of the Islamic empire.

The evolution of empire exhibits excellently the two focal points of law and liberty around which the spiral of political progress ascends in ever shorter and swifter pendulum swings. The imperialist introduction of universal sun worship into Egypt raised the first liberal individualist leader, the pharaoh Ikhnaton, in revolt against clerical conservatism. The rise of a ruling class and religion in the Euphrates valley produced the first lay legislator, Hammurabi. Thus the establishment of larger entities of society such as empires has brought in the first place the emancipation of mind from magic with the establishment of a balance between reason and religion, and in the second place the emergence of a new basis for the state in the consent and cooperation of the individual. Each extension of the larger unity of empire over competing communities, whether Egyptian nomes or modern European nations, is an indispensable preliminary to a period of progress. As soon as the energy of a new race, the economics of a new region or the ethics of a new religion establishes an empire there is an expansion of prosperity and progress.

The golden ages of the world, the epochs

when the state gave the greatest good to the greatest number, seem always to have been during the first imperial alliance of a religious reform with a ruling race. There was such a union during the Asokan age of the Buddhist Indian Empire, the Antonine age of the Christianized Roman Empire and the Abbasside age of the 'Islamized empire of the caliphate. The unity of these empires has left an inheritance of international idealism. The Asokan age still lives in local legend and inspires the ideal of a new confederated and cooperative Indian empire. The Roman Empire still lives in international law and national legislation and has inspired all too many mistaken militarist ambitions for the imposition of world peace. The Islamic state is at the present moment in a crisis of collapse; but its basic principle, the reconstruction of society by a ruling race under a religion regulating the economic energies of every individual and institution, has been adopted so far with success by the newest of empires, the Union of Soviet Socialist Republics. One reason for the success of these empires lies in the fact that although they did not have the externals of democracy, as they are now conceived in polls and primaries and presidents, they had its essentials. There were in them a contact between rulers and ruled, a consonance between reason and religion, a compromise between revolution and reaction, that are sought by democratic ideals and not always secured by democratic institutions. There were moreover that control at the center, that cooperation by an inner circle of the civically conscious and that consent by a mute and unmoving mass that must exist before any group can form or function.

The very different origin of sea empires in early history and the different operation of sea power from that of land power explain why sea empires focus mainly around liberty and land empires mainly around law. Although sea empire began with the commercial and colonizing activities of trading communities like Phoenicia and Crete, it soon entered by way of piracy a phase in which the unifying factor was mainly conquest. So out of the individualist anarchy of the Aegean ascendancy of the tyrants, ruling over insular nations, arose the first sea empire based on mercantile profit and marine police—that of Athens. The mercantilism of the metropolis became increasingly compounded with militarism until eventually the sanction of cooperation and consent was lost and the control collapsed, a history that has since repeated itself.

Nevertheless, sea empires just because both from their political development and from their geographical dispersion they must be unified by consent rather than by coercion must also be in character rather international than imperial. The conditions of sea power always were—and still are—such that if a sea empire became too militarist and monopolizing it could be successfully resisted by a seafaring people of much smaller population and power. Thus did the British and Dutch assert the freedom of the seas against Spanish supremacy.

In a sea empire the ethnic factor, in a land empire the economic factor, will predominate; while the continuance of empire and its contribution to peace and progress will depend on its possession and proportion of the third factor, that of a revitalized—possibly revolutionized—religion. Religion here represents any expression or exploitation of supernatural "magic," rather than of the so-called scientific mind. For example, belief in a mahatma or in a five-year plan is a far more effective factor in the unification of an empire than any belief in heaven or hell.

Unification is obtained and maintained by conquest, by commerce with or without colonization and by consent with or without cooperation. It is the factor of cooperation and consent which makes for permanence in empire, if only because it makes for imperial peace and progress. It is obvious that colonial and commercial empires will contain a considerable element of cooperation and consent until they become respectively too mercantilistic or monopolistic; acceptance will be accorded them in consideration of the advantages they afford, such as the abolition of tariff walls or piratical tolls. Conquest, however, creates very little of this factor of unity, since except in so far as it may bring internal peace it only benefits a ruling minority at disproportionate cost to the progress and prosperity of the ruled.

If this analysis of the unity of empire be accurate it makes possible an estimate of the permanence of existing imperial systems. Such an examination will reveal that an empire lives only as long as it is united, and it is united only as long as it shows it is alive by peaceably and progressively developing both the rights and responsibilities of constituent races, regions and regimes as well as their relationship to the central authority. Thus an empire such as the United States, based on a written and rigid act of union and in process of increasing centralization, may be in a more primitive and less progressive stage of unity

than an empire like the British, in which the relationship is being rapidly reduced to one of sentiment.

The French empire is still predominantly militaristic, mercantilistic and monopolistic. The French nation itself is really an empire-union of four race stocks welded together by war, first against the English and then against the Germans. Its colonial empire is mainly a territorial expansion southward across the Mediterranean over savage Berber and Negro tribes, which it exploits as a mercenary soldiery for the defense of its European frontiers. Its colonial administration is militaristic and frankly mercantilistic; and the principle of unity is that of the discipline, the devotion and the domination of a Roman foreign legion. It provides a Roman peace and a romanesque prosperity both to the burghers and to the barbarians within its borders. But when the French Revolution offered the nation an opportunity to unify Europe in a larger and more liberal empire of confederation and cooperation it failed to achieve more than a brief blaze of conquest. Since then it has learned nothing and forgotten nothing. Indeed its devotion to an out of date ideal of empire unity has become an obstacle to the unification of Europe and will be the origin of the untimely dissolution of its own empire.

The German continental and colonial commercial empire was of much the same character, although on more liberal lines. The unity of its continental corpus held fast under a forging in the furnace of war that found it a reconstituted Holy Roman Empire and will finish it into a corporative commonwealth. But its effort to establish a new European empire of conquest failed as calamitously as did that of the French and for the same reason.

In the United States is also an empire that in its first stage was welded by war into a national unit. There followed colonization of the west from the Nordic east to the exclusion of the French north and the Spanish south. Finally came a national commerce and culture that made the region an economic and ethical entity. But the principle of unity was originally that of an empire, for the political union was created out of sovereign states by the Revolutionary War, while its ethnic and economic unity was a century later imposed by war on the divergent economic interests, ethnic institutions and ethical ideals of the slave states. It may be that the imperialist North thereby established national union at the cost of a larger imperial unity. For

a confederation of northern, southern and western American federations might have been joined by Canadian, West Indian and Mexican federations. Such a commonwealth of North American nations might moreover have found easier of solution that imperial issue, the color question, which now menaces national unity, and that international issue, the question of America's relation to Europe, which now menaces the unity of civilization. The United States is still an empire of conquest in its relation to its oversea dependencies, and in the development of this relation from one of control to one of co-operation it is apparently making the same efforts and the same errors that the British Empire has made.

The internal, imperial and international relations of the British Empire are the most intricate and also the most instructive of any as to the nature and necessity of imperial unity. The ruling island center was based on a union between the English, Scotch, Welsh and Anglo-Irish, with the Irish as a non-consenting minority. In this inner empire the peak of centralization was reached about the middle of the last century. Then came decentralization and after fifty years of conflict the Irish were brought into cooperation as a Free State. Meantime in the less dependent American oversea colonies decentralization had started a century earlier with an economic revolt against the mercantilism and monopolism of the mother country. The secession of the American colonies in spite of the strong religious and racial relationship and the failure of coercion converted the principle of imperial unity and the policy of imperial unification from one of control to one of consent; coercion was replaced by concession as soon as any serious conflict arose. Thus there evolved without much conscious constructiveness except in emergency improvisations a whole congeries of compromises ranging from dominion sovereignty and self-determination to dependencies administered under royal charter or orders in council, with very perplexing and paradoxical results, such as the fact that early racial rivals for empire, like the Portuguese in India or the French in Canada, have become champions of British control. But the British conservatism of all parties has in some cases so delayed concession as to cause conflicts that have carried the non-consenting community into separatism and secession. This may be the case with India. On the other hand, the Boers, Afghans, Egyptians and Irish have in spite of wars of independence been

rewelded through concession into an imperial unity.

Within the central body the growth is still decentralizing, with Scotch, Welsh and some Irish aspiring to the commencement or completion of self-government. But within the newer dominion federations the tendency is toward centralizing power in the federal government as in the United States. Again within the empire as a whole the political tendency is still for decentralization, and the dominions in the Statute of Westminster have assumed sovereign status even as to judicial matters, while mandated dependencies like Iraq are loosing their leading strings by treaty. In India both tendencies are operating simultaneously. Nevertheless, at the same time there is being created within the empire as a result of the economic crisis in capitalist civilization a centralizing movement for cooperation in production and consumption and for control of capital and currency. Although the imperial land power of this commonwealth of nations will never achieve that complete cooperation of its constituents and that cordial consent of civilization which has made its sea power the basis of a future international command of the seas, yet its ununified unity will serve as a bridge between simpler more self-centered national communities and that commonalty of nations that is the only hope of the future.

The most recent and revolutionary of empires, the Union of Soviet Socialist Republics, while still in embryo, has passed through the life history of the imperial unit as above outlined. Its unity was first that of the French Empire, the rallying of a country and class to a revolutionary religion against reaction and repression. Then as in America it became the confederation of sovereign states for defense and development, and the Russian act of union was almost a reproduction of the American document. Thereafter in three years by an extraordinarily rapid evolution of experiment in coercion and concession it grew into a complex of dominions and dependencies resembling in structure and reproducing in system that of the British Empire. Moreover its rapid growth both political and economic are along the same line of economic and ethical unity as that along which capitalist empires are moving.

Imperial unity far from being an antithesis to internationalism has thus far been the only effective executive expression of the international ideal. It is an intermediate stage in human progress from those national units that a scientific civilization has dangerously outgrown to the

unification of civilization now made possible by science.

GEORGE YOUNG

See: EMPIRE; IMPERIALISM; CONQUEST; COLONIES; COLONIAL ECONOMIC POLICY; MERCANTILISM; FEDERALISM; DOMINION STATUS; GOVERNMENT, section on BRITISH COMMONWEALTH OF NATIONS; INTERNATIONALISM.

IMPERIALISM is a policy which aims at creating, organizing and maintaining an empire; that is, a state of vast size composed of various more or less distinct national units and subject to a single centralized will. The conception of an empire as a state composed of many nations leading diverse lives but united by a common ruler goes back to the idea of Alexander the Great of a European-Asiatic empire ruled by a monarch indifferent to the distinctions between Greeks and barbarians, who would be looked upon by both Persians and Macedonians as their own king. National diversity—not national uniformity—and size make an empire, which in addition needs some sort of spiritual cement, be it the personality of a deified emperor, a universal faith (as in the church after Constantine) or the knowledge of a common past and the desire for a common future, often including the consciousness of a "mission." Empires generally break up with the snapping of such spiritual links. In the modern period a new element has come into the conception of empire: the ideal of economic self-sufficiency and "splendid isolation," which cannot be realized within the narrow limits of a merely national state without great sacrifice of material well being but which, it is thought, might be achieved by a judiciously assembled imperial conglomerate of nations.

Empires can be created by voluntary association or by forceful annexation. The process of creating an empire through federation can be called imperialism only if the voluntary act of consolidation has been preceded by the use of more aggressive methods. The reorganization of an existing empire by federative adjustments, a process which is also sometimes called imperialism, is, however, something very different from imperialism as a method of widening a national state into a supernational empire. Although the latter is accomplished chiefly by conquest and annexation, conquest and territorial expansion are not identical with imperialism. Neither the Norman Conquest nor the annexations of Frederick the Great nor the expansion of the American pioneers into the western plains

can be called imperialism; it is the annexation of one nation or state by another with a consequent modification of the structure of the original state in the direction of becoming more or less composite which constitutes the essence of imperialism.

As the use or threat of force is the main method of imperialism, the philosophical justification of the institution presupposes the view that force is an ethical factor. The imperialist creed is founded on the assumption that power is of divine origin and that its wielders are obliged to make humane or semidivine use of it. Thus imperialism, sometimes merely a creed of superior strength, has also been envisaged as an obligation imposed upon those of superior strength, to be used for the benefit of those whom they are enabled to conquer by transferring to the conquered the institutions and teachings with which Providence has endowed the conquerors.

The word imperialism is occasionally used to denote a system of government by coercion under which an imperator—a heaven born or heaven sent leader—rules by a sort of divine right based on heredity and success. It is the element of coercion, the way of governing rather than the aims of government, which may justify this use of the term.

The word has been used in a more specific sense by those followers of Marx since Rosa Luxemburg and Lenin who consider that the capitalist system resists immanent tendencies toward socialism because of its chance to develop non-capitalist areas into capitalist areas. This, they assert, is the result accomplished by imperialism, which is a composite of political pressure and economic penetration made possible by the exploitation of native races. Imperialism thus conceived is a continuation of capitalist exploitation in an age when capitalism is fighting through and for monopoly without having succeeded entirely in wiping out remnants of free competition. Based on the necessity of the export of capital to undeveloped countries, since capital at home no longer yields sufficient profit, it is not a policy to be taken up or dropped at will but an essential aspect of capitalism in its latest—the monopolistic—stage. This view sees the essence of imperialism as the exploitation of native races by foreign capitalists rather than foreign domination of dependencies or the conquest of land by feudal aristocracies, although either or both of these latter conditions may also be present.

Imperialism can best be understood in con-

trast to such policies as that of a national state which objects to expansion and is content with its native territory and a system of rigid self-sufficiency or that of a state which, while willing to exchange products and services for those of other similarly situated states and to base growth and wealth on such commercial intercourse, remains satisfied with its boundaries. There are then two main contrasting systems of national growth: one by territorial expansion and domination (*Herrschaftspolitik*), another by trade (*Handelspolitik*).

Modern imperialism was born with the break up of mediaeval universalism. The states which arose from the disintegrated Holy Roman Empire felt keenly their fragmentary character, and the rise of national self-consciousness brought a desire for expression in a wider sphere. With the Renaissance came the conception of a new man made state which could grow into an empire by following the prescriptions drawn from the Roman Empire by Machiavelli. Although population was not yet superabundant, there was often overcrowding in the big cities and schemes for constructive colonization (the creation of a new society faithfully modeled after that from which it had sprung or of a more perfect commonwealth, some sort of *civitas Dei*) filled men's minds. Such ideas are expressed in Bacon's *An Essay on Plantations*; they are apparent in the various plantations of Ireland and figure vaguely in the aspirations of the Pilgrims. The desire for territorial expansion on the part of the new national states differed essentially from earlier expansionist desires in that conquest no longer served the purpose of achieving private wealth and private fortunes, but that of widening the state boundaries and creating empires by offering new territories to land hungry knights and adventurers.

As discovery and conquest were directed to lands usually inhabited by peoples considered heathen by the conquerors, the missionary idea in the widest sense of the word was not wanting. Not only did the invaders endeavor to convey to the natives the blessings of the Christian religion (an endeavor doubly important since the Reformation had added a competitive note to missionary activities), but they more or less consciously tried to foist upon the natives their own social and cultural systems by "Hellenizing the barbarians" in a particular and national rather than in a universal way. Rivalries waxed strong; each modern nation wanted to extend its newly established nationality overseas in a New Spain, a

New Holland, a New France or a New England by sending out colonists or by assimilating in some degree the native races.

The discovery of the routes to India and America was from one point of view a response to a desire for new commodities, for the satisfaction of new appetites. A money economy arose and with it hunger for gold and silver. To secure gold and silver or goods which would command them became the policy of every government. But purely commercial considerations in the modern sense of the term were not wanting. The desire for a regular flow of goods for home consumption and trade originally dominated; in an age of scarcity monopolies in the spice or fur trade were more important than "open doors," and the chartered companies sought trading profits rather than markets. But as time went on safe access to markets became increasingly important. The winning of the *asiento*, the right to supply Spanish colonies with slaves, in the Peace of Utrecht, was considered one of the greatest achievements of British policy.

While the empire of Charles v, on which the sun never set, was an accidental and short lived conglomeration, the colonial empire which Spain retained was the first realization of modern imperialism. It was organized as a sort of huge mediaeval city-state covering half the universe. The Spanish Empire was to be self-sufficient; the policy of *los abastos*, the aim of which was the prevention of scarcity, was its guiding principle. Trade was rigidly controlled and restricted to the intercourse of metropolis and colonies; foreign traders were considered interlopers. The merchandise of the mother country had the monopoly of colonial markets and the produce of the colonies was destined for the mother country. Control of the precious metals of the New World enabled the Spanish government to carry off the first victory for the nation and for the Catholic church. It was this aim of monopolistic exploitation in the colonies of Spain (and to a lesser degree in those of Portugal) that forced competitors along the path of imperialism. They tried not only to break the Spanish trading monopoly by demanding the right to exchange goods directly with Spanish colonies but also to found colonial empires of their own. Ignoring the Treaty of Tordesillas of 1494, whereby the Spaniards and Portuguese had divided the New World among themselves, the Dutch, the French and the English all laid the basis of colonial empires in West and East.

The mercantilist theory clearly reflects the

twofold desire to support trading rights and to build an empire. Its name implies the view that trade and exchange, not conquest and domination, are natural sources of additional wealth. Its advocates assert repeatedly that countries can become rich in precious metals by the flow of a well regulated trade without assuming responsibility of territorial political annexation. Such trade, controlled by government action or by monopolistic chartered companies, is coercive rather than competitive; and as monopoly seemed to increase profits, coercion and domination came basically to affect relations originally conceived as purely commercial. The Dutch monopoly of the spice trade could not be created without complete domination of the islands where the clove trees grew; trading undisturbed by the whims of native despots was feasible only if the European "factories" were properly protected; out of charter privileges grew intimate financial relations between trading companies and native princes which ended in some sort of protectorate; ultimately came annexation. Although trade and not territory was the aim in these cases, the outcome was empire, the more or less forceful acquisition of new dependencies. The growth and expansion of such empires enabled their rulers to look beyond the profits of trade to those which could be made from exploiting native labor.

There arose a conscious desire to make the empires self-sufficient by a division of labor among the different parts, an aim realized to a considerable extent by the *pacte colonial* and in the early organization of the British Empire, under which England monopolized shipping and the production of wool; Ireland, linen; the plantation colonies, tropical produce; and the northern colonies, lumber and tar. Trade was carried on under a system of preferential duties which favored imperial products; prohibitions and inhibitions restricted foreign commodities, especially foreign ships. True, colonial markets were unable to take over the entire surplus production of the motherland and unwilling to give up cheaper supplies from more profitable markets in foreign countries, while the mother country could neither renounce foreign markets nor refuse additional or essential supplies from them. Nevertheless, there was a fairly well developed imperial scheme embracing various nationalities (although scarcely races, since this first British Empire was, apart from slaves, Anglo-Saxon) and aiming at self-sufficiency by regional economic adjustments. Before its complete break-

down Adam Smith designed a project of empire including the constitutional reorganization of the relations of motherland and colonies by means of an imperial parliament.

The artificial man made mercantilist state collapsed in France not so much because of faulty construction as because of the strain put upon it by French policy. Its failure gave birth to the physiocrats' system, antagonistic to state intervention, colonial acquisition and foreign trade. In England, by that time in possession of the most valuable French colonies, the attack against the colonial system was directed especially against the monopoly of the colonial trade, the chartered companies, which mixed trade with sovereignty, and the military and financial burden laid on the mother country by colonies. While in order to be profitable trade must be free from coercion, coercion of some sort was the mainspring of imperialism. If it could no longer be exercised because colonies would no longer submit to rule by the home government without being properly represented, colonial empires must go to pieces. While the metropolitan democracy fought for responsible government and a wider franchise, the colonial democracy demanded independence. From 1776 to 1822 nearly all colonial empires inhabited by whites were dissolved; conquest and domination were hotly denied as legitimate sources of government. The Monroe Doctrine stopped once and for all the making or remaking of empires on the American continent. Imperialism as a policy of territorial expansion suffered a severe defeat. As a commercial policy it persisted until the industrial revolution enabled the Manchester school of liberals to launch against it a vigorous attack based on a systematic, practical anti-imperialist philosophy. Colonies, the result of conquest and domination in the interest of ruling feudal classes, could be held only at the price of military preparedness and naval supremacy—a costly and aggressive foreign policy. Colonial monopolies must be abolished and free trade replace government control which was making for high prices in the interest of privileged domestic or colonial groups. The battle of the Anti-Corn Law League was less a struggle for cheap bread than an attack on feudalism and all it stood for.

Experience had shown clearly that a successful colonial plantation was unwilling permanently to remain a dependency offering a protected market or furnishing special supplies to a mother country. Imperialism as a commercial policy had failed and was rated so low that even Disraeli,

archimperialist of a later epoch, called the colonies "millstones round our neck." It was succeeded in England by the idea of free exchange making it profitable for new countries to produce raw materials and foodstuffs for the open markets of older countries and to purchase manufactured goods from the old countries rather than to proceed to premature industrialization.

Territorial expansion was not completely stopped. England gained new dependencies in the treaties ending the Napoleonic wars; France annexed Algeria partly to show her people that the splendors of the First Empire had not completely disappeared; masses of Russian peasants surged over the steppes to Siberia; pressure of population started modern mass emigration. The Ricardian theory of land monopoly, that landed interests levied a tribute on all other classes, suggested a solution of difficulties by extending territory overseas, thus reducing rent and exploitation. There arose the idea of directing the stream into the newly acquired virgin lands, which had first served as penal settlements, in order to create a daughter in the image of the mother state. The experiment was tried by the Wakefieldians in South Australia and New Zealand. The lesson of the American Revolution bore fruit: it was necessary to entrust white communities with responsible government if imperial links were to be preserved. The mother country must give up intervention; financial policy and the control of customs and tariffs must be entrusted to the colonists. The hope for universal free trade facilitated this change, which began with the grant of responsible government to Canada. Regional self-government became possible, enabling a daughter state to remain within the empire, politically dependent on the home country but paying no tribute to it, growing up under the empire's powerful protection at the expense of the taxpayers. Empire was conceived as a confederation of scattered states each enjoying responsible government under a constitution evolved by its own people and ratified by the mother country; free nations each at liberty to develop its own national or racial characteristics, all united voluntarily under the leadership of a mother country, in whose most central institutions—sovereign, foreign affairs, defense and supreme law court—they participated in ever changing ways. Apparently the miracle of *imperium et libertas* had been achieved. Although laissez faire and "trust the people" had made possible the development of a Greater Britain, public opinion took comparatively little pride in

the work achieved and political leaders seeing the burdens rather than the benefits doubted the possibility of holding together an empire bound by such loose ties. Expecting dissolution sooner or later, they tried to lessen their responsibilities wherever possible and leaned to the ideal of a socially happy and contented "Little England" waxing rich from unhampered foreign trade and secure in the affections of its inhabitants and in the good will of its neighbors.

In fact *imperium et libertas* had not succeeded completely. While liberty held the daughter states within the political ring of the empire, economically it failed completely. Nearly every young commonwealth tried to bring about its industrial development by high protective tariffs aimed chiefly at imports from the mother country. While enjoying complete liberty of access to English markets it admitted English goods only when it suited its convenience. Economically the empire had split; even the conception of an economic entity composed of various economic provinces joined and developed for the purpose of imperial self-sufficiency had evaporated.

The empire moreover was composed of two completely different elements: on the one hand, the self-governing daughter states and, on the other, countries such as India inhabited by native races. The latter were ruled by a white bureaucracy which strove to administer the surging masses in the way of enlightened eighteenth century despotism, moved often by true missionary spirit which sought not only to free the natives from the fetters of oriental superstition and misrule but to Europeanize them. The natives were moreover taught to believe that penetration and permeation of the alien European civilization were essential to their well being and might lead ultimately to self-government. The growth in England of liberal ideas of justice and economy and the development of democratic institutions made such alien rule appear irrational to rulers as well as ruled, and it was philosophically justified only as a sort of temporary control at the end of which stood independence or partnership.

After 1848 new forces came into motion. Although the subject nationalities which had risen against their masters in central Europe were defeated in 1848 (and again in Poland in 1863), the new nationalist movement could not be stopped. The Austrian Empire was deprived of its Italian provinces and ousted from the German confederation, so that it was no longer supreme

among the Germans and thus no longer able easily to control its various nationalities. The subject races of Turkey revolted to form more or less stable national states. And the Irish, the one people which had withstood the assimilating power of the British Empire, evolved a new nationalism after the horrors of the famine. Liberalism now received a definite setback through Bismarck's phenomenal rise. Once again power, domination and coercion proved themselves reliable instruments of policy in the hands of a master. Force instead of being a method to be used shamefacedly and to be excused only by dire necessity became again an openly acknowledged instrument of policy. The old philosophy which looked upon force not as a last remedy evil in itself but as a method of action glorious in itself was revived.

Aggressive nationalism democratic in its instincts and an equally aggressive statesmanship of dictatorial and despotic origin both needed the development of all economic resources within the confines of their power. Neither could rely on international economic intercourse, in which nations depended on each other for mutual exchange, as such exchange although more profitable in peace than the artificial development of sheltered industries exposed nations threatened by war to grave economic and political risk. The apostles of free trade were discredited and protectionism as a combination of national sentiments, lust for power and individual industrial greed again became rampant. Aiming at a high development of the national agricultural and industrial apparatus, it could not hope to achieve self-sufficiency on the level of a standard of living high enough to keep the industrial masses satisfied without some oversea expansion and colonial exploitation.

The new imperialism differed in many ways from that of the mercantilist period. Although its chief beneficiaries were old established colonial powers, countries hitherto largely without colonial power entered the field. In the cases of Russia and the United States overland expansion across more or less empty spaces had reached natural barriers and became transformed into movements of conquest and annexation of other races. Other states—for example, France in Algeria under the Restoration, in China and Mexico under the Second Empire and in Tonkin and Tunis under the Third Republic—turned to colonial expansion largely to demonstrate to their people that the path of profitable glory was still open. Italy, Germany and finally Japan en-

tered the contest late. Unification or modernization suddenly gave them enormous strength and accelerated their industrialization without enabling them to provide for ever growing populations. Emigration increased; and although many foreign countries were glad to receive white immigrants, the latter were doomed to be lost to the mother country through assimilation. Markets needed for an ever growing surplus of production had become insecure since the decline of free trade. Industries, dependent on supplies from countries subject to foreign domination and heading toward either industrialization or monopolies of raw material, might easily be throttled. Experience seemed to show that trade between mother country and dependencies grew much more rapidly than other trade, and the percentage held by the mother country in imports and exports seemed more secure in more or less nationalized markets. Trade moreover was no longer in cottons or glass pearls but had become a matter of large scale enterprise carried on under contracts and concessions granted by governments and open to nationals by means of properly weighed tenders, even if equal treatment by tariffs was stipulated. Business by concession had become monopolistic.

For the security of capital, which was emigrating in ever increasing amounts to backward countries, open or disguised political control was essential. Moreover a nation without a colonial empire was considered second rate. The control of dependencies to which emigration could be directed might enable a Germany or an Italy to repeat the great feats of the Anglo-Saxons in America and Australia. This romantic idea disappeared rather quickly, for the lands acquired by new colonial powers were inhabited by native races whose collaboration was essential to success. Modern imperialism became more and more a policy of control of native races by conquest and administration (political colonization) and by financial reorganization and capitalistic development (capitalistic colonization). Both forms of control relied on the superior strength or wisdom—if technical skill can be called wisdom—of the ruling race. The stronger dominated, ruled and exploited the weaker in open contradiction to the principles of Christianity and democracy expounded at home. The required philosophical justification of the new order of things was found in theories of biological evolution. The notion became popular that as superiority enabled a race to survive, survival was a God given proof of superiority; ruling na-

tions were superior nations with a right to rule and exploit and to raise the standards of the whole human family. Lust for power and greed of wealth were not absent in this appeal to a natural law, which had changed its meaning somewhat since the day when settlers naïvely assumed that backward people must die out when brought in contact with superior races. Provided they were willing and capable workers they were now made to breed as fast as they could for the benefit of their masters. Imperialism thus justified biologically and morally was not only a policy and a creed; rulership and exploitation became moral obligations. Kipling spoke of "the white man's burden," United States Senator Albert Beveridge proclaimed that "God has made us adepts in government that we may administer government among savage and servile people."

The growth of this biological nationalism meant that imperialism was no longer based on a philosophy of uniting in a common bond of imperial statehood diverse races with equal rights, but rather on a philosophy of tribal supremacy which assumed the existence of racial characteristics largely unchangeable unless through miscegenation. The ruling race might spread the outer technique of its life; the ruled race was unfit to understand its inner quality. Missionary activity, long an integral part of imperialism, lost its soul.

Old saturated powers disinclined to shoulder new responsibilities were often led to do so lest the advent of a new power to the borders of an old possession be more dangerous and more expensive than the expansion of existing frontiers. The result was a scramble for the non-occupied parts of the world, which resulted in the partition of Africa and the distribution of those Pacific islands which had not yet found a master. To cover their rivalry countries went back to some of the time honored political dodges of the mercantilist age, forming private chartered companies to establish rights of sovereignty as a preliminary to government action. The presence of capable native races made settlement colonies impossible. The only choice lay between a native dependency, in which colored people were ruled by a white bureaucracy, and the settlement in climatically favored spots of a planter aristocracy on which depended a small white middle class devoted to commerce and some skilled white labor, while the manual work including small farming was done by the natives. These "mixed colonies" became the social danger

spots where racial animosities and conflicts were bound to arise.

The method of squeezing out an income for the mother country by producing valuable commodities with forced labor, originally perfected by the Dutch in their East Indian colonies, was again adopted. Rivalry in the Congo basin led to the founding of an international private company, the Congo State, controlled and later ruled by the king of the Belgians as a private venture. The Congo basin was internationalized to give equal trade opportunities to all nations signing the Congo State Act. This new international state, precursor of the mandate system, produced an almost unbelievably bloody reign of capitalistic exploitation defended on the ground that the black man must be taught the dignity of labor.

Imperialism is not restricted to expansion of sovereignty or territory. Trade too is developed imperialistically whenever political coercion is used to foster it. When the maritime powers forced the door open in Japan, in China and earlier in the Mohammedan countries of the world and compelled native governments to create treaty ports in which foreigners could trade with natives without being subject to native law, their trade policy was coercive and not competitive, political rather than commercial—in brief, imperialistic. Where native governments weakened, protection of European traders, missionaries or creditors led to the assumption of a protectorate and finally to annexation. International jealousy prevented the annexation or partition of Egypt, Turkey, Morocco, Persia or China. Plans for partition were frequently drawn up, spheres of interest demarcated and non-alienation agreements with native governments entered into so as to postpone such events. In the meantime these governments were reorganized and allowed to live. When backward states disintegrated politically, the ousted rivals among the colonial powers forced the principle of the open door on the winner of the spoils. This obligation, first clearly pronounced by John Hay in 1899 to protect American trade against discriminations in respect to tariffs, harbor and railway rates, was cumbrously elaborated for Morocco by France and Germany in 1909 to include loans and concessions as well. Most governments have insisted on the principle of the open door where they had no chance of exclusive control; wherever partial or full control has been offered them, their attitude has changed. When in 1910 the United States government se-

cured the participation of American capital in the construction of Chinese railways, it substituted for the principle of equal treatment for all that of more or less equal participation of the great powers.

Capitalistic colonization expanded and tended to monopoly. Economic wealth as a form of power became as important as military pressure. To develop their resources native governments needed money or were forced to resort to concessionaires. Lending to native governments created intimate financial, economic and political relations. The creditor country might secure orders for its industries, support for its armament work and employment for civil, financial and military experts. For some time the battle over loans was bitterly fought by bankers through their national diplomats in Turkey, China or the Balkans. Creditors' councils often representing different nationalities in proportion to the sums due were entrusted with the financial reorganization of bankrupt native governments. Certain revenues were handed over to them for the service of the loan (the debtor and the creditor were to share surpluses), and European technical "advisers" were placed in charge of the native administration. Egypt under Lord Cromer was the classical example of this system, which originated in Turkey and was applied internationally in China, Tunis, Morocco, Persia, Turkey and Liberia. In the Central American republics the United States, converted to "dollar diplomacy" as a corollary to the Monroe Doctrine, used it intensively, forbidding European creditors to interfere.

Financial control has enabled foreign powers to run native states without directly assuming political responsibility. The organized but unseen forces of governments are put at the disposal of "visible business." Business enterprises wrest concessions—for railways, for mines, for oil—from native governments, which they keep in power by lending financial support contrary to the interests of the native masses. Occasionally its own capitalistic citizens may embarrass the home government, which in its public policy may prefer friendly political relations and a slower social development to the hidden control of native governments and rapid profitable exploitation of native races.

The World War was called an anti-imperialist war and, especially by President Wilson, a war for the self-determination of nations. The peace put an end to Germany's imperialistic aspirations by depriving her of a colonial empire as

well as of her non-German nationalities. It "liberated" the subject nationalities of the Austrian Empire and tore the Baltic states and Poland from Russia. It limited Turkish sovereignty to the lands of the Ottoman race and expelled the Greeks from Asia Minor. Although the victors divided among themselves the colonial inheritance of the vanquished, the imperialistic system all over the world has quavered ever since. The revived creed of the Manchester school, that the era of domination had passed for ever, had inspired Wilsonian doctrine; the establishment by the League of Nations of the theoretical legal equality of all nations gave flat denial to imperialist claims of superiority. Mandates were created for most colonial territories lost by Germany and for those fragments of the Turkish Empire which although inhabited by separate nationalities were supposedly unable to stand alone. Mandatory powers were entrusted with the government on the theory that they would administer it in the interest of the inhabitants and of the members of the League of Nations, to which equal opportunities in trade were to be offered. Practise has infringed upon the theory of the mandatory system, for egoism or lack of administrative capacity has led mandatory colonial administrations into carrying on and permitting imperialist methods despite international control. The theory of mandates and even of colonies nevertheless continues to maintain that the rule of advanced nations over backward populations is a conditional, transitory trust.

The change of imperialism into a kind of tribal nationalism among rulers raised a similar tribalism among the ruled, who began to deny the superiority or value of the culture of the imperialist powers and to strive to get rid of them. The anti-imperialist crusade against the Central Powers gave them a good chance. The ambition of subject nationalities to be free of their masters could no longer be stifled after the masters had waged a world war theoretically for the acknowledgment of the right to complete liberty. These subject nationalities claimed those very rights for the defense of which they had been asked to enlist. Political imperialism had become self-contradictory. Ireland and Egypt broke away from British rule; India demanded complete self-government; even the dominions insisted on unlimited sovereignty as equal partners with the motherland; and in nearly all European dependencies with the exception of backward Africa there were uprisings for national independence.

All over the world a period of countercolonization began, and decolonization is rapidly proceeding. This movement is not restricted to the struggle of subject dependencies for self-government but is apparent in such former colonies as the Baltic States and Mexico, where natives are ousting from economic and political power the descendants of alien conquerors. It is strongest in countries like China, where imperialism, capitalistic rather than political, had induced or compelled native governments to hand over the administration of customs and taxes or the exploitation of railways and mines to foreigners, whose interests were protected by low treaty tariffs and who were allowed to live in privileged settlements under their own law. In Turkey, China and Egypt attack is directed against privileges for foreigners which were originally exacted from the natives and against foreign capitalists as the chief beneficiaries of these privileges.

In 1927 at a congress in Brussels attended by representatives of radical parties and groups of thirty-seven countries there was founded the League against Imperialism and for National Independence, which issued a call for united mass action and continues to carry on organizational and propaganda work. Anti-imperialist movements have enjoyed the support of the revolutionary Communist International, with which their more radical leaders sometimes cooperate. Since the extortion of high rates of exploitation and the accumulation of great profits are made possible only by paying extremely low wages and keeping the native masses on a low subsistence level, the passions of the newly enslaved victims of the machine against foreign masters and foreign ways readily become the basis of more than nationalist movements. Faced with the opposition of native bourgeois elements who have themselves acquired vested interests in imperialism, such movements respond to Communist influence and are transformed into anti-capitalist movements directed not only against imperialism and capitalistic foreigners but against the inequities of the capitalist system in general. The Marxist-Leninist sees all efforts to mitigate the oppressive effects of imperialism upon native masses as ineffective, and as futile all attempts to deal with the contradictions and war dangers which imperialism creates among capitalist imperialist rivals, on the one hand, and between imperialist and anti-imperialist forces, on the other. This view argues that objectively such attempts are tantamount to support of im-

perialism since they are based upon the assumption of preserving capitalist society. Imperialism and its consequences contribute to the creation of an objective situation ripe for revolution, the only method for terminating imperialist aggression and its attendant evils.

That the imperialist spirit is by no means dead is demonstrated by the desires for conquest and exploitation shown by many nations, especially such hemmed in countries as Japan. The substitution of monopoly for free competition has assimilated the views of the commercial classes to those held formerly by feudal aristocracies. Even the Soviet Union might conceivably use coercion to exploit a backward region. It is the system of imperialism as such—the annexation and rule of dependent nationalities, the policy of creating national wealth by foreign conquest or political and economic pressure—which is being called into question by those who fear that colonial powers are not sufficiently strong or rich to risk imperialist wars against natives who have learned political cohesion and modern military organization. The costs of imperialism have risen enormously; the possible benefits have decreased correspondingly. But while new ventures in imperialism may be of doubtful profit, imperialism may long continue as a policy of consolidating existing empires, perhaps with a view to economic self-sufficiency, wherever the ruling race can eliminate tribal or racial prejudices and is willing to let the subject races share in the empire as partners enjoying legal equality without sacrifice of national characteristics. Capitalist imperialism restricted to mere business aims may still have a long life; but the eclipse of political imperialism is probably final, for there are no new continents on which colonial empires, twice lost, could be raised for a third time.

IMPORT DUTIES. See CUSTOMS DUTIES.

IMPRESSMENT was employed in England from the time of the Plantagenet kings up to 1815 to supplement voluntary recruiting for both army and navy. Soldiers and sailors were thus secured by irregular conscription in the reigns of Richard II and Philip and Mary. Under Elizabeth local justices of the peace were required (5 Eliz. c. 5) to return a specified number of able bodied men for the navy. Charles I and Parliament used the press during the Civil War and Cromwell raised his New Model Army by the same means. Impressment for the navy, however, was far more important and widespread than for the army.

In the usual procedure in naval impressment an order in council was issued authorizing the lord high admiral or the commissioners of the Admiralty to institute impressment proceedings. The Admiralty would then issue press warrants to naval officers. Equipped with these warrants and bearing bludgeons and stretchers, press gangs forcibly seized able bodied men in streets and taverns. Sailors, watermen and dock side laborers were most highly valued. Sometimes a returning merchant ship was boarded and a large part of the crew pressed. In 1776 and again in 1779 a general press of rogues and vagabonds in London and other centers was found necessary because of the great difficulty in recruiting sailors for the Revolutionary War. Occasionally youths were kidnaped by agents in the service and secretly confined until they could be slipped aboard. The East India Company also frequently made use of this method. An act of Parliament in 1795 supplemented these methods by a quota system, whereby each English county and seaport town was required to furnish a specified number of men. When the floating supply of rogues, criminals and gypsies had been exhausted, local authorities offered cash bounties to complete the quota. In 1803 the gangs were required to raise 10,000 men within a fortnight; the ensuing general press stripped every merchant ship in London of its hands and carried off all available watermen.

With certain exceptions all Englishmen were subject to the press any number of times. Men of property, trade apprentices and youths under eighteen who had been apprenticed to the sea by parish authorities were legally exempted, as were the masters of fishing boats and a limited number of their apprentices. In 1740 an act of Parliament exempted all men under eighteen and over fifty-five, all foreigners serving in British ships and all sailors during their first two years of

service. An act of Parliament (6 Anne c. 37, sect. 9) exempted American colonials, but it was occasionally disregarded and was repealed in 1769. A general press of sailors, ship carpenters and laborers in Boston in 1747 was followed by three days of rioting which forced the colonial governor to retire from Boston for safety.

The press was not directed against religious or political nonconformists as such. It did, however, offer countless opportunities for settling personal grudges and for petty extortion. Theoretically, men who felt that they had been illegally impressed were given an opportunity to state their case. Actually, if friends ashore or a bribe to the press officer had failed to free an impressed man, there was scant opportunity thereafter for escape. On the whole therefore the evils of impressment were those of arbitrary impersonal power which struck haphazardly at the liberty of individuals.

The paradox of impressment in a country which was already beginning to think in terms of natural liberties is partly explained on grounds of expediency and economy. As long as the security of the crown rested on a full exchequer it was wasteful and even dangerous to maintain the fighting forces at full strength in peace time. Even after Walpole had restored national finances to a sound basis, however, impressment was not abandoned. Although the greater frequency and intensity of foreign wars might have justified larger permanent fighting forces, public opinion continued to associate a large standing army with tyranny. The Opposition in Parliament made full political capital of this prejudice. Furthermore the general prosperity of agriculture and the expansion of trade and industry offered employment far more lucrative and regular than service in His Majesty's forces. Most Englishmen who sought seafaring careers in the eighteenth century preferred the mercantile marine to a man-of-war. Although attempts were made to attract volunteers through patriotic placards and alluring promises, the greater proportion of men had to be secured by impressment.

While British courts never specifically legalized impressment, Sir Michael Foster [Broadfoot's case, Foster's Crown cases, 154 (1743)] stated: "The right of impressing mariners for the publick service is a prerogative inherent in the Crown, grounded upon common law and recognized by many acts of Parliament." Later Lord Mansfield [Rex v. Tubbs, 2 Cowp. 512 (1776)] deplored the practise but justified it as

necessary for the safety of the state, and Blackstone characterized it as "only defensible from public necessity." In all wars of the eighteenth century impressment was strongly endorsed by both political parties for both the army and the navy. It was ardently defended by statesmen and diplomats in the lengthy controversy with the United States as both legal and necessary. Generally speaking, impressment also enjoyed the sanction of public approval.

Deplorable filth, foul rations, inadequate pay, irregular terms of service and scanty shore leave made service aboard an eighteenth century man-of-war anathema to voluntary recruits. Naval service was rendered even more unpopular and dangerous by the presence of impressed rogues and vagabonds; condemned criminals, who, given the choice of service or the gallows, had taken the former; absconding debtors and prisoners for debt, who so long as they did not owe more than £20 to any one person could escape prison by enlisting in the army or navy. The enforced enlistment of criminals of the worst category created new problems of morals, health and discipline. Outstanding naval officers, such as Admirals Hawke, Vernon and Nelson, branded impressed men as unclean, vicious and potentially disloyal. The disease and filth from jails and slums added to insanitary conditions aboard ship caused serious epidemics which undermined on occasion the effectiveness of entire squadrons. Herded together on the lower gun decks, impressed desperadoes formed gangs to steal, to connive at desertion and occasionally to take part in mutinies, several of which took place in the years from 1797 to 1801. Army officials found impressed men so dangerous that impressment for that branch of the service was abandoned by 1800. In spite of its evils, however, impressment for naval service was continued throughout the Napoleonic wars.

At the outset of this protracted struggle with France, Great Britain had difficulty in keeping her fleets manned even with inferior material. British seamen too were deserting in large numbers to the American mercantile marine, where higher pay and better working conditions obtained. In an effort to secure sailors the British resorted to the practise of stopping neutral vessels even on the high seas and searching them for deserters and for native born British to be pressed into service. British diplomats and statesmen rested their right to do so partly on the logic of necessity but largely on the doctrine of perpetual allegiance, whereby no citizen or subject

of a state could divest himself of his original citizenship without his country's consent, and on a denial of the principle that ships on the high seas compose a part of the territory of a nation. The United States, on the other hand, stoutly asserted full jurisdiction over its ships on the high seas. The situation was aggravated by the continued impressment of native American citizens. The British claimed that the similarity in appearance and language together with the lack of adequate proof of native citizenship and the heavy traffic in birth certificates and "protection papers" made it impossible in many cases to distinguish between native born and naturalized Americans. The number of Americans impressed is difficult to determine; on the basis of the available records Zimmerman estimates the total number of native and naturalized at slightly less than ten thousand. Many of these were released shortly after impressment. The humiliating search of the United States frigate *Chesapeake* in 1807, a peacetime year, and the removal therefrom of several "deserters" accentuated the importance of impressment as an outstanding diplomatic issue between the two countries. American diplomacy hampered by divided public opinion and an inadequate navy failed to secure a satisfactory settlement of the impressment issue. Madison's war message of June 1, 1812, listed impressment as the principal reason for going to war with England. Modern historians, however, have tended to question the fundamental importance of the issue as a cause of the war. Certainly the peace settlement carried no hint of its solution. For some thirty years thereafter the issue continued unsettled. The question lost its practical interest after 1815, however, when Great Britain ceased to impress although without renouncing impressment in principle.

Impressment therefore was abandoned rather than abolished. Great Britain's position as mistress of the seas and of a far flung empire now necessitated large naval forces of a permanent character manned by voluntary recruits. The service became more popular as the causes which had made impressment necessary were gradually removed. From its inception in 1756 the Marine Society had sought to mitigate the worst evils of impressment. The same group of philanthropists who effected prison reform also succeeded in ameliorating conditions aboard ship. Following the War of 1812 seamen were paid regularly in money and at a higher rate, shore leaves were more generously granted and steps taken to eliminate filth, disease and over-

crowding. In 1835 enlistment was placed on a five-year basis with provision for renewal. When at the outbreak of the World War conscription was again resorted to (Military Service acts, 1916-18) it was impartially executed on a nation wide basis.

IMPRISONMENT is the most severe means used by society to curtail the freedom of certain classes of its members. It involves confinement in a prison which places the prisoner under the constant and immediate control of the authority imposing it. It has been and is widely employed for the detention of persons who while not convicted of crime cannot, it is thought, be allowed to remain at large and for the punishment or corrective treatment of convicted offenders against the criminal law. In one of its oldest forms, the origin of which is lost in antiquity, it is used for the custody of persons accused of offenses against custom or statute law. In some states this remained until relatively recent times as almost the only form of imprisonment. As late as 1771 the French jurist Jousse stated that prison was used only to hold criminals before trial and not to punish them even in case of crime. The social significance of such imprisonment is obviously great, particularly since in most localities courts are not always in session. John Howard in his investigation of English prisons in the eighteenth century found prisoners who had been confined for seven years awaiting trial. The average length of confinement for this purpose in the jails of the United States may run into weeks and in isolated instances into a year or longer. Imprisonment is used also for the detention of material witnesses, whose presence at trial can be assured by no other means.

The fact that sentences cannot always be executed immediately upon conviction has necessitated the detention of prisoners until the execution of sentence. This form of imprisonment, also ancient, is most conspicuously illustrated in the death houses of state prisons in the United

States. In case of sentences to forced labor detention is incidental and is usually necessary to assure the execution of the primary penalty. Instances of this form of imprisonment may be found in ancient Egypt and Rome and in more modern civilizations in connection with sentences to the galleys. In substance of course slavery has often been accompanied by imprisonment; the road gangs of the southern states of the United States are strongly reminiscent of this type of detention. Debtors have frequently been subjected to imprisonment in order to compel payment. Particularly during that period of legal history when composition took the place of bloody private vengeance it often became necessary for the aggrieved party to assure the payment of the bot by securing control over the person of the debtor and if necessary by forcing him to work off his debt. Later when the state took firmer hold of the administration of justice, imprisonment of private debtors was frequently allowed and has persisted until recent times. When the bot to the injured party gradually evolved into a fine to be paid to the state by the offender as a punishment for a breach of the peace, imprisonment gradually arose as a means of compelling payment. As such it is still common, having definitely become transformed into a substitute penalty. Imprisonment has also been used to force obedience to judicial decrees as in cases of non-payment of alimony or as a penalty for disobedience against violators of labor injunctions. It is employed occasionally to assure the execution of certain judicial or administrative orders, as, for example, those pertaining to the deportation of undesirable aliens.

Dangerous or undesirable persons have frequently been subjected to imprisonment. Such treatment was not unknown in the Middle Ages and was definitely incorporated into the legislation of the sixteenth and succeeding centuries. In recent decades it has become particularly important, especially outside the United States, as a measure of security (*mesure de sûreté*; *Sicherheitsmassnahme*) against abnormal or habitual criminals, being imposed as subsequent to the completion of punitive imprisonment. Imprisonment has also been used as a primary punishment for convicted criminals, at first probably as a commutation penalty substituted for a death sentence by an act of sovereign grace but later as a punishment recognized by law—a form of imprisonment which is today perhaps the most important if not the most common of all legal punishments.

Punitive imprisonment appears to have been used in China, India, Assyria and Babylon and Egypt. In ancient Greece and Rome it was all but unknown but with the coming of the Christian era its use increased. The church early recognized its value as a penitential punishment for certain offenses against the canon law. Reserved for delinquent members of the monastic orders and the clergy as early as the fourth century, it was soon extended to the laity under the jurisdiction of the church.

From canon law it was gradually translated into civil law. It appeared in England as early as the reign of Alfred (871-901) as a penalty for juvenile delinquents. Among the Langobardians a law of Liutprand in the year 726 decreed from two to three years' imprisonment for theft. It appeared as a subsidiary penalty for failure to pay bot in Lübeck in 1160 and at Brünn in 1243. Imprisonment was, however, rarely used as a primary punishment until the thirteenth and fourteenth centuries. A Nuremberg ordinance of about 1300 punished certain sex offenses with five years' imprisonment and a Cologne ordinance of the same period decreed a year's imprisonment for the breach of a peace order. A number of English statutes of this period also recognized imprisonment for certain types of offenses. In Italian cities it came into use in cases of petty crime during the Renaissance. At this early date it seems to have been employed as a mark of deference to their sex in the cases of certain women offenders and also of nobles as applied to some offenses for which the common man suffered corporal and capital penalties. These distinctions remained until the century of Enlightenment, when the principle of equality of all men before the law was established. Even where it had found hospitable reception in legislation punitive imprisonment was not used to any great extent until the middle of the sixteenth century in England and the beginning of the seventeenth century in continental Europe, and it was reserved for petty offenders. Not until the beginning of the nineteenth century did it succeed in displacing the capital and corporal penalties for serious crimes.

Imprisonment as a punitive measure had to await the development of a social philosophy which considered such a penalty more effective or suitable than others established by custom or law. It could hardly gain much popularity so long as punishment was considered a private matter. Even when the growing power of the state took charge of the administration of the criminal law,

centuries passed before imprisonment was promoted to a place of honor among these penalties. Its use may have been suggested by the right of asylum in ancient cities of refuge or by the practice of the detention of debtors, as contended by Wilhelm Wundt; it may also have been the natural outgrowth of the use of the pardoning power in commuting death penalties and of the preventive detention of dangerous or habitual offenders at the order of the sovereign, as G. Bohne and others have asserted. Whatever may have been the causes for the use of imprisonment in the ancient world, its introduction in mediæval and modern Europe was undoubtedly in large measure due to the influence of the church. By the time of the Renaissance, the individualistic philosophy of which Bohne emphasizes, imprisonment was firmly established as a penalty in canon law. The Reformation, the revolutionary economic changes in the Europe of the fourteenth, fifteenth and sixteenth centuries, which transformed the nature of criminality, and the growth of a humanitarian philosophy which culminated in the egalitarian doctrines of the eighteenth century combined to effect the disappearance of bloody and crippling penalties. To the freeman imprisonment was presumably the most severe of punishments and therefore the most deterrent. To the enlightened legislator imprisonment commended itself by the ease with which punishment could be adjusted by the length of the sentence to the guilt of the criminal and to the degree of enormity of his crime. To an industrial society it seemed eminently suitable as a means of combining punishment of criminals with profit to the state resulting from penal labor; to the humanitarian it appeared as a great advance over the cruelty of older laws and as an opportunity for human salvage.

It is difficult to say when the reformatory or corrective attitude became merged with the concept of punitive or deterrent imprisonment; evidence of this tendency is to be found, however, in documents of ancient China and in the writings of Plato. It was dominant in the canon law; in civil law it appears most definitely in the corrective imprisonment prescribed at the end of the sixteenth century in Elizabethan England and in Holland, whence it spread rapidly. Such legislation considered primarily the youthful petty offender of both sexes. Moral philosophers of the eighteenth century began to demand that imprisonment should always be used as a means of securing the moral regeneration of the prisoner. The climax of these demands is to be found

in the penitentiary movement of the last century.

Despite its conspicuous position in modern criminal law imprisonment is, generally speaking, a punishment reserved for the most serious crimes, and even for some of these crimes many countries are beginning to employ in part other measures of punishment. It is still generally used to detain persons arrested and held for preliminary hearing or for trial who either cannot find bail or are accused of non-bailable offenses; almost three million people pass annually through the police lockups and jails of the United States. Imprisonment as a form of punishment is not only losing ground in some countries, but in late decades sentences have in most jurisdictions grown shorter, indicating a lack of confidence in their efficacy. French judicial statistics, the oldest consecutive series in the world, show that between 1826 and 1830 the annual average of prison sentences expressed in percentages of total sentences was 99.3 for the *cours d'assises*, 18.0 for the *tribunaux correctionnels* and 4.9 for the *tribunaux de simple police*. In 1927 the corresponding percentages had changed to 98.0, 52.0 and 2.2, indicating that most of the serious crimes are still punished by imprisonment; that over half the serious misdemeanors are now so punished; while imprisonment for petty misdemeanors has almost disappeared, there being only 15,000 such punishments out of 704,000 cases in 1927. In all French courts in 1927, 14.8 of the sentences were prison sentences as compared with 13.7 in the years between 1826 and 1830. While the popularity of imprisonment as a form of punishment appears unchanged in France for over a century, the length of imprisonment has changed. Between 1826 and 1830, 2.3 percent of the prison sentences were over seven years in length, 27.5 percent between one and seven years and 70.2 percent one year or less. In 1927 the corresponding percentages were 0.3, 3.6 and 96.1. Furthermore in 1927 20.6 percent of these sentences were never executed. The statistics of Scotland show close similarity to those of France, except that the fine is not so frequently used. Between 1872 and 1876, 37.4 percent of all sentences were prison sentences; between 1917 and 1921, 38.0. In Germany in 1886, 69.4 percent of all sentences for offenses against the imperial laws were prison sentences; in 1928, 30.6 percent. A progressive shortening of the sentence is also evident. In England in 1866, 97.6 percent of the convictions in assizes and quarter sessions were followed by imprisonment, while in lower courts 21.3 percent of con-

victions had similar consequences; the corresponding figures for 1929, 72.7 percent and 4 percent, indicate considerable modification in law and judicial practise. In Canada in 1880, 16.9 percent of all sentences resulted in imprisonment; in 1930, 7.4 percent.

In New York in 1926 a study of felony convictions in representative counties indicated that 69 percent resulted in imprisonment. In Indiana in 1929, 74 percent of the felony convictions were so punished. The superior courts of Maine sent 43 percent of their convicted defendants to prison in 1930. The following table derived from a pioneer study of the Johns Hopkins University Institute of Law shows the percentage of cases for which higher courts in Ohio and Maryland, dealing with the more serious offenses, specified imprisonment as a penalty in 1930:

| | Ohio | Maryland |
|----------------------------|------|----------|
| Homicide | 84.5 | 89.5 |
| Rape | 83.2 | 77.2 |
| Robbery | 82.4 | 92.8 |
| Aggravated assault | 72.0 | 79.8 |
| Burglary | 68.0 | 84.3 |
| Larceny | 63.4 | 76.4 |
| Automobile theft | 63.6 | 86.9 |
| Minor assaults | 35.2 | 67.2 |
| Forgery and counterfeiting | 64.0 | 74.2 |
| Embezzling and fraud | 50.3 | 72.0 |
| Carrying concealed weapons | 64.7 | 71.1 |
| Sex offenses, except rape | 70.6 | 20.1 |
| Offenses against family | 29.8 | 8.0 |
| Liquor law offenses | 7.4 | 29.4 |
| All offenses | 55.0 | 54.3 |

The absence of adequate judicial statistics in the United States makes a study of the trends in sentencing policies almost impossible. Statistics published by the United States Bureau of the Census, in so far as they are comparable, indicate that the sentences of prisoners received in federal and state prisons and reformatories for adults in 1923 were of an average minimum length of 2.37 years and a maximum of 7.69 years for males and .9 years minimum and 4.49 years maximum for females. The corresponding figures for 1927 were for males 2.12 and 7.66 years and for females .67 and 4.30 years. Although the data are too meager to permit any conclusions, there is reason to believe that even in the United States imprisonment has progressively declined as a punishment for minor offenses and that even in the case of felonies other forms of treatment, such as fines, probation and suspended sentences, have in recent decades become widely employed. Imprisonment is still the preferred punishment for felonies in all civilized nations;

comparative studies of criminal law show, however, that in so far as its application to specific crimes is concerned no uniformity whatever exists, because of the fact that the concern with which a given type of offense is regarded by a given community is determined by that community itself and usually on emotional and irrational grounds.

Imprisonment is widely defended for its deterrent value and its importance in restricting the liberty of dangerous criminals. A study of the records of recidivism of prisoners throws serious doubt on the former contention. Statistics indicate furthermore that the indeterminate sentence, parole and judicial discretion in assigning definite sentences have resulted in relatively short periods of punitive confinement for all but certain groups of offenders. In 1927, for instance, the average time served by prisoners discharged from federal and state institutions for adults was only 2.18 years for men and 1.33 years for women. Recent researches into the careers of prisoners after their release from prison also challenge the reformative powers of this penalty, and while the validity of the source may be questioned, autobiographical records of erstwhile prisoners lend strong support to the claims of penologists. Many of these have come to suspect that social virtues can never be taught in the repressive atmosphere of the traditional prison and that even at its best a prison offers slight opportunity for rehabilitating criminals in the face of inadequate financial appropriations, the general apathy and even hostility which meet the prisoner on his release and the progressive shortening of sentences; this last development while perhaps beneficial to the prisoner in view of the present status of prisons makes the process of socialization in the institution increasingly difficult.

Some states have provided funds for the indemnification of persons who have been wrongly imprisoned; others occasionally meet a particular case by the enactment of a private law. In most states, however, no provision has been made to compensate such persons for loss of time, liberty and social prestige—a survival of an old doctrine that the sovereign can do no wrong.

INAMA-STERNEGG, KARL THEODOR VON (1843-1908), Austrian economic historian and statistician. Inama studied political science, history and jurisprudence in Munich and was appointed professor of political science at the University of Innsbruck in 1868. There he devoted himself primarily to the opening up of new sources of economic history and prepared the publication of *Die tirolischen Weistümer* (3 vols., Vienna 1875-80) for the series of *Österreichische Weistümer*, a collection of customary laws which had been undertaken by the Vienna Academy of Sciences. As a preparatory work to this he published *Untersuchungen über das Hofsystem im Mittelalter* (Innsbruck 1872) and "Die Entwicklung der deutschen Alpendörfer" (in *Historisches Taschenbuch*, 5th ser., vol. iv, 1874, p. 99-169). He also published studies *Über die Quellen der deutschen Wirtschaftsgeschichte* (Vienna 1877) and "Über Urbarien und Urbarialaufzeichnungen" (in *Archivalische Zeitschrift*, vol. ii, 1877, p. 26-52), which were of use in agrarian historical research, and laid down his

interpretation of the agrarian history of the early Middle Ages in *Die Ausbildung der grossen Grundherrschaften in Deutschland während der Karolingerzeit* (Leipsic 1878). In 1879 appeared the first volume of his *Deutsche Wirtschaftsgeschichte* (3 vols., Leipsic 1879-1901; vol. i, 2nd ed. 1909), a pioneer contribution to the discipline of economic history, which was then in its beginnings, the subsequent volumes of which dealt with the latter Middle Ages. Inama represented from the very first an evolutionary point of view in that he considered all the conditions of the present to have grown gradually out of those of the past. In accord with the general view of the time agrarian history was for him the most important phase of economic history. A leading representative of the *hofrechtliche Theorie*, Inama stressed the fundamental significance of the manorial system (*Grundherrschaft*) for the economic and social organization of the Middle Ages and traced the origin of early mediaeval industry and the rise of towns, markets and guilds to the institution of the manor. A few years before his death he founded the *Österreichische Urbare* (1904), published by the Vienna Academy of Sciences, which reproduces the sources of agrarian history of the Middle Ages with explanatory tables and maps.

Inama entered an entirely new field of activity when he was appointed to the direction of administrative statistics in Vienna in 1881. As president of the Central Statistical Commission from 1884 to 1905 he directed the Austrian national censuses of 1890 and 1900 and essentially improved statistical methods, introducing for electrical tabulation a machine of Austrian invention which was superior to that of the American Hollerith. He widened the scope of statistical inquiry, founded the *Österreichische Statistik*, of which seventy-six volumes appeared during his tenure of office, and established the annual *Österreichisches statistisches Handbuch*. He collected Austrian city statistics according to a unified plan in the *Österreichisches Städtebuch* and the statistics of the autonomous local governments in a separate publication. Inama also founded a research seminar in statistics at the University of Vienna, where he taught as honorary professor of statistics; the seminar functioned as a training center for the entire pre-war generation of Austrian statisticians.

ALFONS DOPSCH

Consult: Mischler, E., in *Schmollers Jahrbuch*, vol. xxxiii (1909) 1129-59; Rauchberg, H., in *Zeitschrift für Volkswirtschaft, Sozialpolitik und Verwaltung*, vol.

xviii (1909) 1-28; Below, G. von, in *Biographisches Jahrbuch und deutscher Nekrolog*, vol. xiii (1908) 116-24, listing Inama-Sternegg's works, and in *Vierteiljahrschrift für Social- und Wirtschaftsgeschichte*, vol. vii (1909) 167-71; Juraschek, Franz von, "Vierundzwanzig Jahre der statistischen Zentralkommission Österreichs unter von Inama-Sterneggs Leitung" in *Statistische Monatsschrift*, vol. xxxii (1906) 1-13.

INCEST is illicit sexual relationship between persons within the degrees of consanguinity excluded from such relationship by socially determined regulations. The penalizing of some forms of incest is characteristic of all human societies; the varying intensity of the punishment is largely determined by the degree to which the practise of incest interferes with the social obligations essential to the maintenance of the social structure. The law against incest is rarely enforced in modern societies with the vigor with which the correlate amongst many primitive peoples is enforced, for no modern society is based upon affinal obligations to the same degree as are most primitive societies. In many of the latter the consanguine group, small or extended, of unilateral or of bilateral descent lives sundered from other similar groups except for the interrelationships that attend intermarriage. In the absence of a highly developed political organization social organization depends on the performance of the obligations attached to relationship. A separation of affinal relationship from consanguineous relationship assures a wider recognition of social obligation, for the former relationship carries with it such obligations as alliance in war and cooperation in hunting and in mourning ceremonial. Any incestuous alliance between two persons within a single consanguineous group is in so far a withdrawal of their consanguineous group from the alliance and so endangers the group's survival. Because in modern society the obligations attached to affinal kinship are not extensive and those attached to consanguineous kinship are restricted, rules against incest such as those contained in the Anglican prayer book are not all enforced by the state; but incest between consanguineous kin who are still within the restricted circle of real obligation remains liable to severe penalty. Aristocracies are an exception; although they require, when impoverished, affinal association with the wealthy of other classes, they nevertheless do not frown upon sexual relations considered incestuous by other groups.

Theorists as diverse in outlook as Freud, Westermarck, Brenda Seligman and Briffault

have dealt with the theory of incest from the point of view of the internal organization of the procreating group. Freud takes the family as it is constituted in modern European society and draws a picture of a belligerent father opposing a son's incestuous desire for the mother. The son's incestuous desire is suppressed and the force of the revulsion drives the son's desires away from home. The dynamics of these forces are supposed to be rooted also in a primitive society in which the father possessed many women and drove the sons from home by his own main force, an apocryphal state of primitive society which has never been actually described in fact. Malinowski has given a description of a meek father in a matrilineal society, a fairly frequent primitive type, which negates Freud's theory.

Westermarck's theory of incest is that inbreeding is biologically harmful and that there is in the human race an instinctive aversion to incest, which is aroused by familiarity through the close proximity of members of a family. Inbreeding, however, is not known to be biologically harmful except amongst stocks which are too poor to stand an accentuation of their qualities. Furthermore, while it may be true that familiarity does not arouse sexual desire, such familiarity must be of a non-sexual character. If, for example, brothers and sisters in any society were encouraged to sexual familiarity in childhood there is no evidence that sexual aversion would develop between them. Brother and sister are, however, encouraged to sexual aversion from early childhood in most societies. In some societies a stringent avoidance between brother and sister is set up in childhood and maintained throughout life; this would lead to sexual attraction, were Westermarck's theory correct. Actually the avoidance functions effectively in prevention of incest. Once the terms of a familiar relationship are set up, further familiarity develops the relationship whether it be sexual or antisexual. Westermarck appeals to knowledge of a familiar relationship that is culturally antisexual to derive a theory of natural sexual antipathy within it. But the antipathy is a cultural product just as a complete avoidance between brother and sister is a cultural product. In modern society a complete avoidance between brother and sister is not enforced in childhood as it is, for example, in the Trobriands and in Samoa, because in modern society sexual habits are not allowed free expression and early formation. Westermarck therefore in urging an influence of familiarity presupposes the terms of

the familiarity which are socially determined in an antisexual direction, and which are not an explanation but a subject for explanation.

Brenda Seligman like Freud bases her case on the constitution of the family. The father protects his sexual rights in the mother from the son. The mother protects her sexual rights in the father from the daughter. The parents, prevented by each other from incest with a child of the opposite sex, prevent the children from incest with each other. A father, for example, who is denied incest with his daughter denies his daughter to his son. Incest is held to destroy discipline between the generations by arousing jealousies and competition in place of authority and cooperation. Briffault presupposes a universal primitive matrilineal state. Mothers loved their sons and required their children to cleave to them, as occurs in any matrilineal society. The mothers were successful in keeping their daughters at home and in preventing their sons from loving any women but those at home. The sons to gratify sexual desire had to break with the mother and so married away from home. The jealous mother in this theory replaces Freud's jealous father.

All of these theories revolve about the internal constitution of the biological family of parents and children, which is found very widely in different societies, although not so universally as the prohibition upon incest. Where the biological family and the prohibition of incest are both found it is rare for the field of the latter to be confined to the former. If the prohibition of incest is to be explained in terms of family jealousies or aversions it must be assumed that the range of operation of these jealousies and aversions is expanded beyond the family—on occasion into a unilateral clan or gens, sometimes into an extended bilateral kinship group and occasionally into three out of four or into seven out of eight classes of consanguinity. The inference is that neither jealousies nor aversions are the prime determinants of the social forms concerned in the regulation of incest. The founding of a theory of incest upon the supposed effects of the practice upon the internal structure of the procreating group is a theoretical overelaboration of the restricted range of incest which is found in modern society. In practically all societies, however, penalties upon incest are not motivated by the damage done within the incestuous group by the incest. The penalties are imposed upon the offenders by the wider society as a protest against the offense of disturbing social cooperation; there

are usually no such penalties imposed on other analogous provocations to jealousy in families.

The marriages of kings often differ considerably from the marriages of commoners in regard to what is considered incest. The king represents a social group much wider than his actual consanguine group, although in some societies all of a king's subjects are reckoned as his consanguine group. There was royal incest in Egypt and in Hawaii, although in Hawaii the king married twice, once incestuously, the second time further afield than his subjects. In incestuous marriage the king indicates the independence of his blood and of his kingdom. In marriage further afield than is the custom of his commoners the king acts like any one of his subjects in the latter's more restricted orbit; he makes an alliance between his own group and another group. When a king fails to make this latter type of marriage, his marriage is usually regarded as morganatic. There is greater similarity from this point of view between the morganatic marriage of a king and the incestuous marriage of a subject than there is between the incestuous marriage of a king and the incestuous marriage of a subject, for a morganatic marriage fails to produce an expected alliance between social groups just as does the subject's incestuous marriage.

In unilateral societies where social organization divides a kin into different social groups which may then often be reunited by affinal ties, marriage is frequently contracted between the children of siblings of opposite sex, where sexual relations between the children of siblings of the same sex are regarded as incestuous; for the children of siblings of opposite sex belong to different groups whether marriage residence be patrilocal or matrilineal and social organization patrilineal or matrilineal. Bilateral social organization, which involves a wider consanguine group in the relationship function, commonly makes all sexual relationships within the bilateral group, except that of husband and wife, incestuous.

INCOME consists of services, which can be defined as desirable events or the avoidance of undesirable events. Under services may be included benefits from a property right, such as the interest yield of a bond; the benefits derived from objective instruments, such as the shelter afforded by a dwelling, or from the cooperation of individuals with such instruments, as the transportation service of a railway; and the services rendered by individuals whether they be manual laborers or professional men. The value of an income is the value of the services of which it consists; it is measured for practical purposes in terms of money.

Since income in general is a set of services, any particular kind of income is merely a specific collection of services selected in accordance with certain principles for a definite purpose. Thus the total income of an individual is the total money value of the services received by him from all sources including his own activity, while the dividends during a certain period of

time yielded by a certain preferred stock owned by him is a definite separable set of items out of his total income. Similarly a person's net money income is the sum of all his money receipts, less the money invested. This is equal to the money he spends; for all money received must be either spent or invested.

The income of society as a whole is the total money value of all the services received by the members of society from all sources. The concept of social income, however, does not, as might at first be suspected, involve double counting; for in the summation of any group of income items many items will be found to be negative—debts instead of credits. Certain events, which may be called interactions, are at the same time services and disservices, according to the point of view. These cancel out automatically (in cases where both points of view are included) under the principles of double entry bookkeeping. For instance, when yarn from a spinning mill is transferred to a weaving mill to be woven into cloth, the value of the yarn is credited to the spinning mill as a service and debited to the weaving mill as a disservice, or cost. To the owner of the spinning mill the transfer is income; to the owner of the weaving mill the same item is outgo, or negative income. If the same man owns both mills, the interaction between the two mills counts both ways and is canceled out of his accounts. So also it cancels out in society's collective books.

Most events are interactions; so that in a comprehensive view most services are also disservices and cancel out, leaving as a final uncanceled fringe only the psychic experiences—enjoyable or distasteful—of the consumer. When everything is included, every item except these experiences of the consumer appears as two, pairing off as an interaction, and automatically cancels out. If this theoretical bookkeeping were to be carried to the bitter end, it would be necessary to include items in private life which cannot be reduced to money valuations. But for practical purposes it may be possible to exclude from this accounting the events in the private life of the consumer. Thus instead of pursuing him into his dining room and recording in the theoretical accounts every process of his eating and drinking, the economic observer may be content to stand outside and keep account only of the food as delivered by the grocer; he will record the money valuation of the food although he can not appraise its later consumption. This restriction does not alter fundamen-

tally the principles of summation; it simply leaves uncanceled a different fringe. Instead of the highly theoretical psychic satisfactions emerging in a complete analysis the net result now turns out to be the highly practical "real wages" of the laborer or more generally the "real income" of an individual; that is, the value of his expenditures for food, clothing, shelter, amusements and other miscellaneous services representing the last stage measurable in money before the state of private consumption.

Real income may be said to be the peg on which all other valuations hang. All interactions anticipate real income and by the process of discounting derive their valuations from it. Thus a capital balance sheet at any given date is obtained by discounting (capitalizing) expected real income. It is made up of assets and liabilities. Each separate asset consists of the present value of a separate bundle of services expected in the future. Each liability consists of the present value of future disservices. Capital is simply the algebraic sum of a given collection of assets and liabilities; that is, of positive capital and negative capital. To be complete the collection should also include goodwill in the technical sense of the excess of the valuation of the prospective services of the enterprise considered as a whole over the mere sum of the valuations which are assigned to the assets when considered separately.

One important result of these principles of income computation is the exclusion of capital gain from income. The capitalization at any point of time of future expected income is not itself income, and by the same token an increase in this capitalization from one point of time to another is not income—except potentially. Thus if \$1000 in a savings bank is earning \$40 a year and if the depositor actually withdraws his interest earnings every year, the actual income from his savings bank account is \$40 a year and the principal sum is the capitalization of this income in perpetuity; but if he does not withdraw the interest this amount is merely accrued and becomes capital gain, or savings, rather than income. If the interest accruing at the end of the first year is left in the bank, the interest earned every year thereafter would be \$41.60. The depositor's actual income is then zero the first year and \$41.60 thereafter (if he withdraws it) and not, as often carelessly thought, \$40 the first year and \$41.60 thereafter. That is, at the end of the first year \$1040 is the then discounted value of the \$41.60 a year thereafter; and at the

beginning of the first year \$1000 is the then discounted value of this same \$41.60 a year without counting any income in the first year at all. The amount of \$1000 is certainly not the discounted value of an income of \$40 the first year and \$41.60 the second and every subsequent year thereafter. The accrued \$40 is not income but the difference between two capitalizations; namely, \$1040 at the end of the first year and \$1000 at the beginning. It was only potentially income; that is, it could have been withdrawn without diminishing the value of the original capital. The depositor had to choose between taking it out as income or leaving it in as capital; by preferring the second alternative he increased his capital at the expense of present income. No essential change is introduced if the depositor actually takes out the accrued interest and then immediately redeposits it. If its receipt was income, its redeposit was certainly outgo; so that the net income is still zero. Nor will it make any difference if the amount is redeposited not in the original bank but in another from which he receives \$1.60 a year interest thereafter. Merely to use two banks does not change the net effect.

It is right and proper, however, that accountants should set up ideal standards and reckon potential as well as actual income. Such standards are often more useful to business than the exact recording of actualities with all their irregular fluctuations. Indeed much of an accountant's work consists in smoothing out irregularities. To absorb the shock of unusually big items he spreads these over long periods by means of reserve accounts, sinking funds and other accounting devices; also unusually small items may be eked out. Potential income is so convenient for comparison as to merit being called income so long as it is made clear that this income is not actual.

From the point of view of the stockholder stock dividends and some split ups do not represent income, for a stock dividend is equivalent to a money dividend actually received and then immediately reinvested in the new stock. It is true, of course, that a stock dividend, especially if received regularly, may be sold in the open market and turned into income exactly comparable to cash dividends. But such realization of the potential income represented by the stock dividend is possible only at the expense of investment by someone else, the buyer of the new shares received as dividends. Whether capital gain and stock dividends are income is not sim-

ply a question of theory; it has important practical consequences in connection with the income tax (*q.v.*) and under certain conditions it has been a rather important factor in stock market movements.

Certain peculiarities attach to income from labor as contrasted with income from property. Thus in computing the income of a servant girl it would be necessary to include not only her wages but also her perquisites—board and lodging—for these are a part of her compensation in addition to money wages. On the other hand, from this total should be subtracted a valuation of disservices, the irksomeness of her toil; practically this would be as difficult, of course, as directly to value psychic satisfactions. Furthermore accountants do not usually depreciate the income of a working man as they depreciate that from a work animal or a machine; for they cannot easily appraise the value of a human being. So that, whereas the accountant's standard of income from capital is a perpetual annuity, his standard for a human being is the current income earned. Because of these difficulties the income from labor as stated in terms of money is always larger than it would be if the computation of income from property were taken as the standard procedure: it does not allow for the depreciation of a human being as a source of labor power nor for the negative value of distasteful experiences connected with labor. If accountants could put a money value on psychic phenomena and human wear and tear, it would be more readily recognized that the grand total of all incomes is simply satisfactions less the efforts of obtaining them.

The concept of income developed above is most closely identified with the work of Irving Fisher. It incorporates into a self-consistent theory the accountant's and business man's view of income and capital; and it can be easily articulated with theories of value and distribution which represent a specific adaptation of the marginalist approach to the usages of a highly developed business economy. While it is coming to be more and more accepted by economists and accountants it cannot be said as yet to represent the *communis opinio* of all or even most students. Like many other concepts of general familiarity and fundamental importance in economics, income is still a controversial subject; and the fact that income must be defined for taxation purposes and actually has been so defined in many jurisdictions in a variety of ways

does not help matters. For the kind of income that is to be taxed is largely determined by the economic organization of a country and the fiscal needs of its government. Even the economist's view of income is influenced to a certain extent by the type of economic activity which he observes about him. It is not to be wondered at therefore that the mercantilist's notion of income resembled the balance of profit on the merchant's books at the close of the year and that the physiocrats boldly identified it with the *produit net* of the progressive agricultural entrepreneur. Adam Smith's classic definition of "gross revenue" as "the whole annual produce of . . . land and labour" and of "net revenue" as "what remains free . . . after deducting the expense of maintaining first . . . fixed and secondly . . . circulating capital" (*Wealth of Nations*, bk. ii, ch. ii) is in its turn suggestive of the attitude of a competent man of affairs in the period of incipient industrialism.

The thought expressed in the second part of Smith's definition of net income—"what without encroaching upon their capital they can place in their stock reserved for immediate consumption"—was widely accepted during the nineteenth century as the most essential characteristic of income. Its identification of income with the measure of ability to pay taxes seemed particularly opportune at the time when the faculty doctrine and the income tax were becoming increasingly popular. For practical taxation purposes this definition, however, was not sufficiently precise, and numerous efforts were made to clarify it. For example, it left unsettled the question whether chance gains such as legacies, gifts, lottery gains and the like were to be properly regarded as income and taxed as such. The answer was sought by some in the direction of restricting the definition. Income was made to include only those accessions which a rational economic subject might treat as properly available for consumption; or only such receipts as might be expected to recur regularly (Gustav Cohn); or accruals from permanent sources which by their very nature promise a regular and fairly even yield (Adolf Wagner); or in an even more generalized form the product of gainful activity. Other authorities sought a broader definition which would include aleatory gains under taxable income. Perhaps the extreme of this school of thought is represented by G. Schanz, who regards as income the entire difference between the value of assets at the end of the fiscal period and their value at the beginning, thus

including every accretion—in money or kind, regular or irregular, from continuous or temporary sources—deducting only interest payments and capital losses. A more general phrasing of the same thought is the concept current in the German literature at present according to which income is the increase in the economic power of the individual or corporate entity during the period in question. Whatever the value of these concepts for taxation purposes, it is fairly clear that they fail to establish the distinction between income and capital; the broader definitions do not even attempt to draw such a distinction and the narrower concepts depend upon a conventional definition of capital for this distinction. Nor do any of them offer the possibility of a unified treatment of all economic phenomena from the point of view of the flow of services and disservices and its capitalization in time.

INCOME, NATIONAL. See NATIONAL INCOME.

INCOME TAX is a tax on the income of the taxpayer. The term, however, is used in two senses. It may refer to a tax on the income from a special source like wages, interest or rent or to a tax on the entire income from whatever source derived. In the one case it is called a partial income tax, in the other a general income tax. A general income tax, like a general property tax, is a personal tax, or a tax on the person, whose ability is measured in this case by his entire income, as in the other case by his entire property. A partial income tax, like a specific property tax, is indeed paid by some person—the recipient of the income or the owner of the property—but only in relation to a particular source of income or a specific piece of property. For a partial income tax there is no generally accepted name. Both the specific property tax and the partial income tax are really semipersonal taxes as distinguished on the one hand from the purely personal taxes, where there is no reference to any particular thing, and on the other hand from the impersonal taxes, like a tax on tobacco, where there is no reference to any particular person.

The income tax is generally regarded as a direct tax. In the United States the constitution requires direct taxes to be apportioned according to representative population. The term was therefore long interpreted to mean only poll and land taxes; the Civil War income tax was accordingly classed as indirect. When, however, the income tax of 1894 was adjudged to be a direct tax (*Pollock v. Farmers' Loan and Trust Company*, 157 U. S. 429, 158 U. S. 601), it required a constitutional amendment to make an income tax possible.

History. The income tax is an essentially modern phenomenon. Its origin is closely associated with the development of commerce and industry, with the widespread diffusion of the money economy and the consequent emergence of new forms of wealth which could not be reached by older forms of taxation. In early communities ability to pay taxes is measured in terms of property. As real estate was supplemented by personalty the original specific land tax everywhere became a general property tax. Under modern conditions of industrial life property no longer suffices as a criterion of taxpaying ability. The merchant relies to an increasing extent upon the rate of turnover; the entrepreneur is influenced by speculative and other aleatory gains; the laborer, now divorced from the means of production, is dependent solely on his wages; the salaried and professional classes live on their

earnings; the wealthy learn to distinguish between varying rates of return on their investments. The test of ability is shifted from property or capital as a fund to income as a flow of wealth. Income becomes the paramount criterion of prosperity. The general property tax decays, until it is replaced by the general income tax.

The adoption and successful administration of the income tax further presuppose a fairly advanced stage of political organization and the existence of political institutions which are conducive to the development of a considerable degree of cooperation between the community and the state. Accordingly the income tax is found for the first time in the commercial democracies of mediaeval Italy. But with the victory of the later feudalism and the downfall of democracy the income tax soon disappeared. In its modern version the tax did not appear until the end of the eighteenth century.

The modern income tax has traversed four stages: (1) as a sporadic resource in war, (2) as a temporary addition to regular revenues, (3) as a permanent source of revenue and (4) as the chief reliance of the fiscal system.

The first important example of the general income tax as a sporadic war measure was the so-called compulsory loan in France in 1793. More significant was the British tax imposed by Pitt in 1798 and abolished amid universal rejoicing in 1816, at the conclusion of the war. Of a similar character was the American income tax of 1864, the first of the Civil War taxes to lapse by limitation in 1872.

The income tax in peace time dates from the 1840's. Baselstadt in Switzerland introduced an income tax in 1840. In 1842 Peel reintroduced the income tax for three years in order to compensate for the repeal of the corn laws. Austria followed in 1849 and Italy in 1864.

In Great Britain fiscal necessities caused the periodical reenactment of the income tax, until the question of its permanent retention was fought out in the campaign of 1874. The third stage thus attained in England was reached elsewhere in the next two decades. Democratic Australasia was the first to follow the example. South Australia initiated the income tax in 1884, New Zealand in 1891, Tasmania in 1894. In the meantime Japan had created an income tax in 1887; and the German commonwealths, with Prussia in the lead, in 1891. The Netherlands followed in 1893. The United States enacted an income tax law in 1894, but it was declared unconstitutional in 1895; an income tax was adopt-

ed again in 1913 after the passage of the Sixteenth Amendment.

The income tax reached its highest development during and after the World War. The increased fiscal burdens of the war and post-war period coupled with the outburst of the democratic and socialistic sentiments characteristic of the post-war era led to the adoption of income taxes in all the new states created by the peace treaties and to sharply increased rates in the older countries. Today the income tax has become the sheet anchor of the revenue system in the most advanced countries. In the United States and Great Britain it is by far the outstanding source of revenue. In 1918 and 1920 in the United States the income tax together with the excess profits tax produced about 59 percent of the total ordinary receipts of the federal government. Its yield declined to about 49 percent in 1925 but rose again to 58 percent in 1930. In Great Britain the income tax yielded 29 percent of total tax receipts in the last pre-war year, about 50 percent in 1925-26 and about 43.5 percent in 1929-30. Even in France and Germany, where the war exigencies have compelled resort to the sales tax, it is of the greatest importance. In the post-war years in Germany its yield amounted to about 35 percent of total ordinary receipts, while in France its yield rose from 13 percent of total tax revenue in 1920 to 30.5 percent in 1925, although it declined in 1928 to 21 percent. In post-war Italy the income tax produced from 30 to 40 percent of total tax revenue.

Even in the separate American commonwealths the same tendency is apparent. The primitive general property tax began to disintegrate in the more advanced states a few decades ago. While there are earlier sporadic examples of partial income taxes, the modern movement, apart from the experiment in Wisconsin in 1911, really dates from 1919, when the income tax in New York replaced the general property tax as the important source of revenue. The income tax has since then been adopted in part or in whole in a continually increasing number of states.

Types of Income Taxes. There are three chief types of general income taxes, which may be termed respectively the presumptive, the composite and the unitary type.

The presumptive income tax is best illustrated by the first British attempt in 1798. There existed at that time various taxes on expenditure, known as assessed taxes. On the assumption that a man's income can be roughly inferred from his expenditures the law provided a scale of rela-

tion of actual expenditure to presumed income. In class A, comprising persons who owned "establishments" consisting of carriages, horses or men servants, the income was presumed to be from three to five times the expenditures. In class B, comprising persons primarily assessed on houses, windows, clocks or watches, the income was presumed to be from one fourth to five times the expenditures. In class C, comprising persons who paid only on shops or lodgings, the proportion was from one tenth to twice the expenditures. Because of this threefold arrangement the tax was called the triple assessment. The presumption proved to be so inaccurate and the frauds so gross that the tax was abolished after a year to be replaced by a tax resting on actual rather than presumed income. In recent years the presumptive income tax is found only in countries where the economic and administrative conditions render the exact ascertainment of actual income difficult. Thus Greece after experimenting with another type adopted the presumptive income tax in 1921 and Belgium followed suit in 1930. In France this device is utilized only in the case of resident foreigners, where the control of actual income is not easy. The criterion, or presumption, is usually house rent; Belgium also utilizes furniture, servants, horses, automobiles and boats as criteria.

The composite income tax is a tax composed of a series of separate quasi-personal taxes, assessed on the particular sources of income with a superimposed personal tax on the income as a whole. This type of income tax is found in France and Italy.

In France when the old personal taxes were abolished in the revolution they were replaced by semipersonal taxes (*impôts réels*). Taxes were imposed on land, houses, business and the like and although payable by the owner were assessed without reference to his citizenship, residence or personal situation, such as indebtedness or the number of dependents. When the income tax was adopted in 1917 France, adding a few more of the same kind, grouped these specific taxes into six schedules according to the source of income with a different rate on the net proceeds or the income from each of the six sources. These levies constitute a series of so-called schedular taxes. While no attention is paid to indebtedness and little or none to the demands of graduation, a concession is made to considerations of personal ability to pay through exemptions corresponding to the minimum of subsistence and allowances for dependents. It is for this reason

that they may be called quasi-personal taxes; they are not quite personal in character, but almost so. In addition, however, to these *impôts cédulaires* the individual is also subject to a tax on his income as a whole (*impôt général* or *impôt global*), ascertained by combining the results of the schedular amounts. Here ample attention is paid to personal ability, through a system of exemptions, allowances, abatements and graduation; this is therefore a strictly personal tax.

In Italy, where real estate was still subject to the land tax, the income from other sources was tapped in 1864 by the so-called tax on the incomes from movable wealth (*imposta sui redditi della ricchezza mobile*) arranged in three categories or schedules. These schedules were gradually increased in number; to one of them the income from land was transferred in 1925. At present there are six schedules. In 1919, however, these schedular taxes, which now received the name of normal taxes on incomes (*imposte normale sui redditi*), were supplemented by a complementary tax on the entire income (*imposta complementare sul reddito complessivo*), to which a graduated scale was applied.

The composite income tax possesses the advantage of permitting in each separate schedule the most appropriate method of collection as well as a finer differentiation in rate. But it is rather complicated and suffers from the resemblance of the schedular taxes to the old taxes in rem.

The unitary income tax is best illustrated by the income tax system in the United States and Germany. Here the returns are indeed arranged by categories or rubrics according to the source of the income, but the separate items are then simply added together and the rate applies to the resulting total income. In Great Britain the categories or rubrics are more definitely divided into so-called schedules—A and B comprising income from the ownership and occupation of land respectively; C from public securities; D from trade, industry and professions; and E from public salaries and pensions. But this is primarily an administrative device, intended to facilitate the varying methods of collection. With the exception of a reduction permitted for agricultural incomes there is no difference among the schedules in rates, allowances, deductions and the like. The British tax, although often misinterpreted, is properly to be classed with those of Germany and the United States rather than with those of France and Italy. It is almost a pure personal tax, and not a combination of personal and quasi-personal taxes as in France.

The unitary tax is the most prevalent type of income tax; it is more adequate than the presumptive tax, simpler than the composite tax and is most suited to "tax minded" communities which are willing definitely to accept income as the best test of personal ability. A modified version of the unitary income tax applies in Soviet Russia, where progressive rates imposed on the income as a unit are differentiated according to the class status of the taxpayer.

Of limited application are the partial income taxes. These are primarily subsidiary taxes intended either to supplement the general property tax, as in the Swiss cantons, where the partial income tax is used to reach wages and professional earnings, or to replace parts of the general property tax, as in Massachusetts, where a partial income tax is levied on intangible personalty, with a much lower rate on professional or trade incomes. In some countries this form of taxation is applied to reach corporate income. In other countries partial income taxes are used to reach special forms of earnings or profits. In this category there may be included a miscellaneous assortment of taxes, such as taxes on government securities, taxes on chain or department stores when assessed according to net profits and perhaps even taxes on certain forms of real estate levied according to net returns. These taxes, however, are of minor significance and scarcely come within the scope of income taxes in the usual sense of the term.

The Concept of Taxable Income. As an economic concept income denotes a flow of wealth during a definite period, as opposed to capital as a fund of wealth at a distinct point of time. It may be defined as the money or money's worth which comes in during a definite period over and above the expenses of acquisition. The fiscal concept of income, however, is still subject to dispute. In the nineteenth century Hermann and Schmoller elaborated the free disposition or consumption concept, which regards as income only those receipts of which an individual can dispose without impairing his capital. More common outside Germany was the periodicity concept, which would limit income to regularly recurring receipts. The broadest definition of income for taxation purposes was formulated by Georg Schanz in 1894 and was independently advanced over two decades later by R. M. Haig, who defines income as "the money value of the net accretion to one's economic power between two points of time." This view is in substantial agreement with the accountant's practise of as-

certaining the annual profit of an enterprise by comparing the balance sheet at the opening and the close of the year. As a reaction to Schanz, Strutz and Fuisting developed the source concept (*Quellentheorie*), which would confine taxable income to receipts from permanent sources.

With the exception of the income taxes in Basel and in Bremen, where the broader concept was almost wholly accepted, fiscal practise at the outset inclined toward the narrower interpretation of income. In the course of time, however, the concept was widened, the characteristic of regularity disappeared, while chance or aleatory receipts were subjected to supplementary taxes. At the present time findings, occasional earnings or lottery prizes are everywhere included in income, while inheritances are separately taxed, in part because they constitute irregular or accidental income. Special taxation of gifts is also widespread but is sometimes frustrated by administrative difficulties, as in the American experiment of 1922. Neither the permanence of the source nor the regularity of the receipt any longer forms a necessary part of the concept of taxable income.

The widening of the income concept, however, brought forth a number of difficult problems. The first problem is that of appreciation in value. Is this income or only addition to capital? In the light of the Schanz concept it undoubtedly is income. Theoretically this view seems sound. The fact that the gains are added to capital account is no objection. All saved income becomes capital; but until it is saved, it is income.

There are, however, some practical difficulties in the way of accepting this conclusion. In the first place an income tax is supposed to be paid out of income. But if the taxpayer's entire wealth consists in the house that has appreciated in value, he has no funds with which to pay the tax. If he is compelled to dispose of the house at forced sale, his estimated gains may vanish. Moreover his paper profits this year may disappear through a depreciation of value next year. If he has to pay a tax this year, he is not reimbursed for his loss next year. This objection might be removed by an adaptation of the American "net-loss" provision. Such losses are now permitted to be carried forward. They might perhaps also be carried backward.

The deduction of losses from income may, however, prove embarrassing in two ways. One of the weaknesses of the income tax is the fact that in periods of depression when the government is in especial need of larger revenues to

meet emergency outlays the yield diminishes. This disparity is accentuated by allowing losses to be deducted. Secondly, it is only human to minimize gains and to accentuate losses in making the returns. Unless there exists an almost perfect system of control, the government stands in the long run to lose more by permitting depreciation than it will gain by insisting on appreciation. To the extent, however, that the administration improves, this argument loses its force. The abundant returns of the American income tax in the years of prosperity were in no small measure due to the capital gains provision.

A further objection is to the effect that in case of a change in the general level of prices the money worth of a commodity at the end of the period may be greater than at the beginning. The owner may then be assessed for what is nothing but a fall in the value of gold. This objection might, however, be removed by reference to an index of prices, as is done in some of the foreign unearned increment taxes.

Finally, as capital gains are usually taxed when realized through sales or other disposition, the tax tends to retard the sale of property and securities in times of inflated prices. In the great American boom of 1929 this perhaps played a part in prolonging the inflation. But this consideration is of minor importance.

While the arguments are very close, the balance from the practical point of view seems to be in the direction of non-inclusion. It is of course not to be denied that capital gains increase the ability to pay and should be reached. But it seems better to tap this increased ability in some other way than by a regular income tax—just as inheritances, which also increase the taxpayer's ability, are taxed by separate death duties. The increased value of real estate is automatically taken care of by a property tax and can be still further reached by the so-called unearned increment tax. If it is desired to reach personal property gains also, this can be accomplished by the so-called increment property tax. Both of these seem preferable to the attempt to reach the gains directly through the income tax.

This indeed seems to be the tendency in fiscal practise of recent years. Most countries refuse to regard capital gains as income. Germany did so in the law of 1920 but abolished the provision in 1925, although the law retained the tax on capital gains arising from speculative transactions and continues to tax gains arising from the sale or liquidation of the entire enterprise. In France the taxing authority formerly included capital

gains in the tax on securities and has continued the practise in the schedular tax, but it refuses to do so for the general income tax. In Great Britain this practise was never followed, although capital gains were included in the Excess Profits Duty of the war. The United States included realized capital gains in the law of 1913 but has been engaged ever since in whittling away the inclusion. The 1921 law provided that the net gain arising from property held for more than two years might at the option of the taxpayer be omitted from his ordinary net income and separately reported for the imposition of a tax at the rate of 12½ percent; and a movement is now on foot further to reduce the rate.

A still more disputed problem is the relation of stock dividends to taxable income. If a corporation in lieu of paying dividends in cash distributes its earnings in the form of scrip or stock dividends, is this taxable income? As far as the corporation is concerned it is clear that if profits have been earned it is immaterial whether they are added to capital or distributed in cash or in scrip. The receipt of income is independent of its distribution. The problem arises with the shareholder. Are stock dividends a part of his income?

On the affirmative side it is urged that stock dividends constitute an accretion to the economic power of the recipient and as such are an element of taxable income. To tax cash dividends and exempt stock dividends is unjust and discriminatory. Furthermore it may enable corporations to allow their stockholders to escape taxation.

The argument against the inclusion of stock dividends in taxable income is that a stock dividend is unrealized or inchoate gain. The recipient is no richer than he would have been if there had been no stock dividend at all, but a simple allocation of the corporation's income to its surplus. The wealth of the stockholder is measured by the product of the number and the value of the shares. If the distribution is made to surplus, each share is worth so much more; if the distribution is made in the form of stock dividends, the number of shares is increased but not the value of each. While in both of these cases the foundation is laid for increase in future income, there is no addition to present income as in the case of a cash dividend. Nor is there separation of gain. Separation is a necessary attribute of income. If capital is the stock which yields the income or if the capital is regarded as the capitalization of present and prospective income, the inflow of enjoyments must in order to

constitute income be separated from the capital while leaving it unimpaired. In a stock dividend there is no more separation of the assets than in the case of addition to surplus, where the shareholder receives nothing. In an addition to surplus there is no separation of gain: it is merged into and coalesces with the surplus. So in a stock dividend, while there are more paper certificates, there is no separation of assets. A stock dividend therefore is only unrealized and unseparated gain, or inchoate income. To make it real income it must be both realized and separated. In the United States the Supreme Court accordingly declared stock dividends non-taxable under the income tax. They should be reached but, like capital gains, under an increment property tax.

Another disputed point is the problem of including savings in taxable income. John Stuart Mill claimed that to include savings in income is to impose double taxation—a tax first on the entire income and then again on the yield of the income that has been transmuted into capital. This contention, which has been renewed in recent years by Einaudi and others, suffers from several defects. First, it rests on a confusion between the receipt and the disposition of income. Income may be either spent or saved; but both these actions are subsequent, not anterior, to the receipt. One must have the income before he decides what to do with it. The concept of income is independent of the use to which it is put. Secondly, the double tax argument is a fallacy. In the first year a tax is imposed on the entire income from whatever source derived; in the second year there is similarly imposed a new tax, which is now increased because of the additional income. This is not taxing the same thing twice, it is levying taxes on different things; namely, the successive and therefore different incomes. If the individual prefers to save rather than to spend his income, his preference is evidently due to the anticipated advantages of his action. But these clearly augment his ability to pay. To refrain from taxing the proceeds of the capital into which the income of the previous year has been transmuted would involve the abandonment not of a double tax, but of a single tax. Thirdly, if savings are not taxed as income then the income tax is transformed into a tax on expenditure, which is the least defensible of all the criteria of ability to pay. While a poor man indeed spends less than a rich man, the disparity in outlay bears no proportion to the disparity in wealth. The richer a man is, the more difficult it is to spend his income and the more automatic his savings

become. To tax both Henry Ford and his seven dollar a day employee on their expenditures would be a travesty of justice: the latter has to spend virtually his entire earnings; the former, even with the best of will, can spend only a fraction of his profits. For these reasons no country has ever seriously entertained the idea of excluding savings from taxable income. The exemption of insurance premiums and the isolated instances of the exemption of certain types of saving deposits may be defended on quite different grounds.

Quite an opposite suggestion was advanced by J. A. Hobson, urging that only so much of income should be deemed taxable as constitutes a true surplus. By surplus Hobson means "all rents and all gains for the use of capital, brains or labor which are not a necessary incentive to secure such use." But the essential vagueness of this concept and the almost insuperable difficulties of application, coupled with the well nigh practical identity of the results with those of the existing system of graduated income tax and exemptions, have combined to prevent any hearing for the suggestion.

Since income denotes net receipts, there are many border line questions as to permissible expenses. Many of these problems have been solved as a result of recent progress in the theory of accounting. But when the income is derived from the use of permanent capital goods, further allowances have to be made for depreciation, obsolescence and, in the case of natural resources, for depletion.

Precise computation of net income depends on the degree to which the returns can be freed from the admixture of capital ingredients. In a city plot this admixture is almost entirely absent. In a house the annual rental includes an element which represents a partial disappearance of capital through use. In any enterprise utilizing capital goods the upkeep of the depreciation account figures among the allowable expenses. In a railroad or industry exposed to rapid change an additional sum must be charged to obsolescence due to the shortening of the economic life of the piece of capital by a new invention or by new economic conditions which result in the substitution of something more effective or more desirable. In natural deposits like mines or oil wells, where the complete exhaustion is only a matter of time, the yearly output includes a much larger fraction due to depletion. An essential attribute of income therefore is that it must be so defined as to exclude the impairment of the capital. Otherwise the so-called income would include a periodic

fraction of the capital, with the result that in the end there would be neither income nor capital.

Fiscal practise as a rule provides for such allowances. As they do not lend themselves to precise measurements the allowances are somewhat arbitrary. In the United States the law provides for a "reasonable allowance for the exhaustion, wear and tear of property used in the trade or business, including a reasonable allowance for obsolescence." In both cases the test is the "useful life" of the asset in question. In oil and gas wells the statutory allowance for depletion is $27\frac{1}{2}$ percent of the gross income but not in excess of 50 percent of the net income.

Finally, there is the problem of so-called service or satisfaction income; that is, income derived by the farmer who consumes a part of his produce and the home owner who lives in his own house. If a man receives rent for his house, it is undoubtedly income. Consequently if he occupies it himself it would seem that the rental value is likewise income. Similarly farmer A may devote part of his profits from wheat to the purchase of vegetables, while B may plant less wheat in order to raise his own vegetables. In principle the value of B's vegetables ought to be included in his income, but in practise it is not easy to determine their exact worth. As a consequence few countries include house rent and almost none farmer's produce in taxable income. In the United States the farmer's produce occupies a middle position; the part of the crop which is consumed by the farmer is not taxable, but neither can he deduct expenses involved in raising the crop. The universal practise of not including these items in income, while perhaps theoretically invalid, is practically defensible.

In the light of the preceding discussion on the theoretical and practical limits of taxable income the concept can be defined as follows: taxable income is that amount of wealth, in money or easily calculable money's worth, which irrespective of its disposition comes in during a definite period in a separate and realized form over and above the expenses of acquisition and, if derived from capital, without any impairment thereof.

The Subjects of Taxation. The problem here is whether taxable income includes more than the income of the individual. There are two chief aspects of this problem: the relation of individual income to the income of the household, and the status of the corporation in income taxation.

The distinction between the income of the individual and the joint income of the house-

hold is of practical importance under a system of rate graduation: the same total income pays a smaller graduated tax with separable liability of the family members than if assessed as a whole. The manner in which such income is to be taxed should depend on the economic and social organization of the respective country. Where the old patriarchal family still survives, the household is obviously the proper tax unit. In modern times, however, adult children have acquired households of their own, so that they are everywhere subject to individual taxation. So far as concerns husband and wife few foreign countries have reached the American position of the well nigh complete economic emancipation of women. As a consequence most foreign countries provide for joint returns, while the American law permits separate returns. It is only in the eight commonwealths of the United States still subject to the survival of French and Spanish legal theories that the institution of so-called community property is found. This contrast between American and foreign practise must be borne in mind in comparing the real burdens of a nominally equal tax rate.

Far more difficult is the problem of corporate versus individual liability. As to the facts, three main systems may be distinguished: a tax on either the corporation or the stockholder, a tax on both or a division of the tax between the two. In practise this results in six types: (1) taxation only of the corporation without reference to the individual, as in the United States from 1909 to 1913; (2) taxation only of the individual, as in those countries where there is a personal income tax but no corporate tax; (3) taxation of the corporation with the obligation to deduct the tax before paying over the dividends to the individual, as in England; (4) taxation of both corporation and individual with the exemption of dividends from normal personal income tax only, as in the American federal tax; (5) taxation of both corporation and individual with the exemption of dividends from both normal and super-tax; (6) taxation of both corporation and individual with no exemption for the personal income tax, as in New York.

This difference of practise arises from the confusion of underlying theories. According to one theory income is a unit to be treated as a whole. The income of a corporation is the income of the shareholders. To tax the corporation is therefore to tax the shareholders, whose dividends ought accordingly to be exempt. Under certain conditions this theory is tenable. If the corporation tax

is levied at the same proportional rate as the personal tax, it is immaterial whether the dividends are reached in the one way or the other. But in a graduated tax it is different. If both the corporate and the normal personal tax are, for example, 5 percent and if the individual's income from dividends would place him in the 20 percent surtax bracket, it is clear that if only the corporation were taxed and dividends were exempt this would mean an indefensible privilege to the security owners. It is for this reason that the second method was adopted.

According to this method income is not treated as a whole, but is subject to partial separation. In both England and the United States the result is reached, although in different ways, that the corporation pays the normal tax while the stockholder pays the surtax or supertax. This method is defensible on the theory, accepted in England, that income is a purely personal, individual matter and that the collection of the normal tax from the corporation is a purely administrative device of reaching the income of the stockholder. But it is not defensible on the theory accepted in the United States, which recognizes the existence of a corporate income—a theory due largely to the fact that the "corporation excise" tax existed from 1909 to 1913 before the advent of the personal income tax.

This consequently leads to a third theory, which is at present only inadequately apprehended—the theory of complete separation. This theory regards the corporate tax as something entirely independent. A corporation tax is a tax on the corporation itself as an entity, a tax in rem. If the tax on the individual is a personal tax, the tax on the corporation is a semipersonal tax. It may be defended legally as a tax paid for the corporate privilege or as a tax on business in the corporate form. A tax on business as such is something quite separate from a tax on personal income. Since the taxes are disparate phenomena, there is no need of any correlation between their rates and certainly no reason why the corporate tax should be deducted in whole or in part from the personal tax. The question of the incidence or effects of a corporate tax upon the income of the stockholder, while indeed to be considered by the legislator in framing the details, is no more germane to the real problem than is the incidence of any other tax.

The conclusion to be drawn is that while in any event the deduction of dividends for super-tax is unjustifiable, the legitimacy of deduction for normal tax depends on the decision whether

it is the policy to have a business tax. Where, as in the United States, this question is virtually being answered in the affirmative, it would seem that the practise of New York state in counting dividends as income is more correct than that of the federal government. There is just as little reason for deducting dividends because corporations are taxed as there is for deducting the income from land because there is a land tax. The business or corporation tax like the land tax is a tax in rem. The income tax is a personal tax on income from whatever source derived.

These considerations should also suffice to solve the problem of partnership income. The difficulty arises from the fact that far less progress has been made in accepting the partnership as an entity separate from the partners. Almost everywhere the taxation of the partnership carries with it the exemption of the partner. Yet in proportion as the business tax is recognized as applicable also to non-corporate business this difference of treatment is bound to disappear.

The Rate and Amount of Taxation. The rate and amount of the income tax are influenced by three facts—the acquisition, the possession and the disposition of the income.

Differences in the mode of acquisition are responsible for so-called differentiation of taxation, a feature which occurs in connection with other taxes as well. In the income tax the chief difference referable to the origin or acquisition of income is that between earned and unearned income, or, as it is variously expressed, between precarious and fixed, labor and property, unfunded and funded or temporary and permanent incomes. Gladstone called the second class "lazy incomes."

Differentiation, although urged at the outset of the British income tax and especially stressed by J. S. Mill, was not accepted until 1907. In the United States it was also urged in 1913 but not adopted until 1924. At present the reduction on incomes up to \$30,000 is 25 percent. On the other hand, Italy had adopted the idea in 1864, dividing incomes into capital, mixed and labor incomes. In 1894 a fivefold division was adopted. After further changes in 1919 and 1925 the incomes were divided into six categories with differential rates for each. In France the same result is reached by the sixfold schedular taxes. In Germany and some other countries differentiation is achieved by adding to the uniform income tax a small property tax, thus subjecting incomes from property to an additional burden. It has been suggested that the United States accept the

Franco-Italian method at least in part by intercalating between earned and unearned incomes a third category of mixed incomes.

The rate of the income tax is also affected by differences in the amount of income in the possession of the taxpayer. Gradation of the rate according to the size of the income is known as graduation or progression. In the taxation of income the entering wedge of graduation is found in the minimum of subsistence. This soon developed, as in Great Britain, into the system of abatements for the lower incomes. A somewhat similar method was introduced in Prussia in 1891 when the rates on incomes below 100,000 marks were tapered down from 4 percent to zero. The progressive scale for normal and higher incomes was not adopted in Great Britain until 1909. In the United States the federal tax of 1913 started out with a slightly graduated scale of rates, the amount of which rose with the size of the income in each succeeding bracket. In France the same result was reached by the law of 1917, which applied the maximum rate to all incomes over a certain sum with a deduction of one twenty-fifth of taxable income for each successively lower bracket. The war everywhere witnessed an extreme development of the principle, the maximum rate at one time reaching 77 percent in the United States and 60 percent in various other countries. Almost everywhere, however, subsequent legislation reduced the rates.

The graduated principle is less applicable to corporations for the reason that there is a more limited possibility of utilizing the concept of taxable ability. If the corporation tax is regarded as a means of reaching the shareholder, it is obvious that progressive taxation is out of the question. If the corporation be regarded as a separate entity with an independent taxpaying ability, a difficulty arises from the choice between the amount and the rate of the profits as a criterion of this ability. A large corporation will have a larger income; but a smaller corporation may have a much greater rate of return on its capital and in this sense possesses a greater ability to pay. If finally a corporation tax be considered a business tax in rem, there is no more reason for applying the graduated plan to it than to the land tax. It is largely for these reasons that most corporate income taxes are proportional rather than progressive. The state of Wisconsin is a notable exception.

The practise of allowing for differences in the disposition of income started with the exemption of the minimum of subsistence. With the rising

standard of life in modern democracies, however, there has been a widening interpretation of the term minimum, from a bare to a decent living. The entering wedge provided by the exemption of the minimum of subsistence was soon pushed further so as to include expenditures for the wife and children. Wider family considerations led to additional allowances, which have been carried furthest in Great Britain, where they include dependent female relatives, housekeepers and the like. A still more significant enlargement of the doctrine is found in the British allowance for children in college, in the German allowance for doctors' bills and maternity expenses and in the widespread exemption of life insurance premiums with its implication of the social advantage of thrift. None of these is as yet accepted in the United States.

From this it is but a step further to allow for outlays which ought to be encouraged from the broadest point of view of social progress. Examples are the allowance for charitable benefactions (granted in the United States only if not made to individuals, and restricted to a maximum of 15 percent), dowries, gifts to political parties (as in Germany) and interest on war damages. A counterpart to this is the increase of the rate in the case of socially undesirable expenditures of bachelors, divorced persons and childless couples, as found in France.

This interesting development, which is only in its earliest stages, discloses what amounts to a broader concept of income. Just as the refinement of fiscal theory replaced gross by net income, so the pressure of modern public opinion is gradually replacing net by what may appropriately be called clear income. Just as net income is that which comes in over and above the expenses of acquiring it, so clear income may be defined as that which comes in over and above the socially legitimate or desirable expenses incurred while acquiring it. In this sense clear income is just the reverse of the concept suggested by Mill, Einaudi and others. In their view the tax should be remitted on savings; in this view the tax should be remitted on expenditure, to the extent at least that this remission conduces to social progress. Modern democracies steer straight toward the concept of clear income.

Administrative Methods. In the administration of the modern income tax there have arisen a number of problems pertaining to methods of assessment, collection, selection of the tax period, time of payment and size of administrative area.

The most convenient method of assessment

and collection is presented by the system of stoppage or collection at source. It was introduced by Pitt in 1799 in order to prevent the wholesale evasion which characterized the tax of the previous year. Under this system the attempt was made to assess the tax as far as possible on the person who paid the money over to the recipient of the income. It was largely for this reason that the schedular system was adopted. As slightly modified in 1803, in schedules A and B the tax was levied on the occupier, who was authorized to deduct it from the rent due. In schedules C and E, interest on public securities and public salaries and pensions, the tax was deducted by the government. Even in schedule D, trade, industry and professions, where the system was not completely feasible, it was introduced as far as possible by having the corporations, bankers and others pay the tax before turning over the dividends or interest to the security holders. This system of hitting as far as possible the payment rather than the reception of income was so successful that when the tax was reintroduced in 1842 the stoppage at source method was again adopted. Where the tax so collected is greater than the total tax liability of the particular taxpayer, he may apply to the government for refund. The British authorities are unanimous in believing that this explains the success of the tax.

When the United States imposed the federal income tax in 1913 an attempt was made to introduce the British system. But the economic conditions proved to be dissimilar. Real estate was far less frequently rented; and the concentration of financial control was such as to impose onerous obligations, with a high cost of collection, on the firms and institutions which handled the machinery for distributing dividends and interest. The system of stoppage at source was therefore soon converted into that of so-called information at source, whereby employers, rent payers, bankers and the like are bound only to report the amount paid rather than to withhold the tax levied. In the United States collection at source is now retained only in the tax free covenant bonds (where the corporation has agreed to pay the tax for the bondholder) and in the case of fixed or determinable, annual or periodic, payments to non-resident aliens. In Germany collection at source is found in the case of wages and the interest on government securities. In most of the American state income taxes even the system of information at source is absent. In New York it is found only in the case of wages.

Where the tax is levied directly on the recipient of the income, the assessment usually takes the form of an individual declaration subject to some degree of official review. Different countries disclose various stages in the development of official scrutiny and control. In some countries, for example France, where the memories of the outrageous abuses of the *ancien régime* are not yet forgotten, this official scrutiny is reduced to a minimum with a correspondingly large amount of evasion. In Italy the situation is still more unsatisfactory. On the other hand, in countries like the United States public opinion now acquiesces in rigid official control which goes so far as to permit domiciliary visits and inspection of accounts together with actually enforced prison penalties for detected evasion. In the United States there is as a consequence little evasion among the wealthier taxpayers, whose income returns, generally prepared by accountants, are carefully checked by government inspectors. The most successful example of the cooperation of official control with the taxpayers' representations is found in the administration of schedule D in the British income tax.

The usual tax period for which income returns are made is the period of a year. A difficulty, however, arises from the fact of oscillating income: where the income of one year is succeeded by a net loss in the following year, the taxpayer receives no rebate; his taxable ability for the two-year period is not faithfully represented. This consideration has led to the adoption by several countries, including England, of the method of taxing the average income received for a definite number of years—generally three, sometimes more. Objections have been raised to the average system on the score of its not representing the actual income. The British income tax commission of 1919 after discussing the arguments recommended that the average system be abandoned and that the basis should be the previous year, but that allowance be made for losses by permitting repayment where the losses for the following six years exceed the income for the taxable year; this proposal, however, was not adopted. In the United States a concession to the theory of average income has been made since 1921 by providing that the "net loss" of one year may be deducted from the net incomes of the two following years.

The choice between the calendar year and the fiscal year as the basis of the return is largely a question of administration versus taxpayers' convenience. From the point of view of adminis-

trative uniformity the calendar year is the simpler; but where businesses have for good reasons adopted another period as their fiscal year, the latter is obviously preferable. Accordingly, several countries, including the United States, permit the substitution of one for the other.

A similar problem of convenience is raised by the choice between the method of accruals and the ordinary method of actual receipts in the computation of income. While corporate accounting has now become fairly uniform in the leading countries, there is still much divergence in the practise of individuals and especially among the professional classes. It does not make much difference which plan is followed, as long as the same plan is followed from year to year. Most countries require such uniformity.

Most countries also permit the payment of the tax in instalments, running up to four or more in number. Insistence on payment in a lump sum may be embarrassing for the government as well as for the taxpayer. Payers who receive their income periodically find it far more convenient to pay the tax as the income is received. Moreover the diversion of the entire tax from the money market on a single day and the presence in the public treasury of a huge and unnecessary surplus may create obvious difficulties.

Almost all countries provide for complete secrecy. The only argument in favor of publicity of returns is that apart from satisfying the curiosity of the public it may possibly serve, through the general knowledge of one's neighbors, as a deterrent from underdeclaration. But with the many possibilities of legitimate avoidance, if not evasion, that are found in almost all income tax laws this argument is deprived of much of its validity. On the other hand, publicity leads to unnecessary disclosure of what are essentially private concerns and intensifies the opposition to all inquisitorial examinations. The experience of the United States with publicity of returns in 1924 and 1925 was not a happy one, and inspection of the returns is now permitted only in the case of the officials of states which themselves have an income tax.

All successful income taxes depend upon central rather than local administration. Local administration of certain taxes has much to recommend it where objects of a local situs or persons with a fixed residence are dealt with, and where the detailed knowledge and experience of local assessors are helpful. But income is difficult to localize and the shifting of domicile from one locality to another is easy. Moreover local assess-

ment is more exposed to the danger of political pressure or favoritism. In federal countries the further problem presents itself as between state and federal administration. In countries, for example Germany, where the paramount question because of reparations is that of federal finance, the empire collects the entire income tax, which is then apportioned in part to the states and subsequently still further to the localities. Even in other countries where the economic basis of income has become national, where the difficulties of double taxation have become acute and where interstate business is constitutionally exempt from state taxation much may be said for federal administration. But where, as in the United States, not all states have as yet adopted the income tax, where the state needs are so diverse and where the feeling of state rights is still so pronounced, it will probably take some time before this administrative improvement is adopted. In the interval a decided improvement can be effected by applying the device already utilized in the inheritance tax; namely, granting to the states that levy an income tax a credit of a certain percentage of the federal levy, the rate of which can be increased for that purpose.

The Relation of Income to Property Taxation. In countries which still levy a general property tax or which impose special taxes on real estate there are some important special problems arising out of the relation of income to property taxation.

The first question is: should the income from real estate be deducted from the taxable income? This problem has assumed special importance in the American state income taxes. The argument is advanced that inasmuch as real estate is already subject to the property tax, to include the income of real estate would impose on it a double tax. The contention is invalid. If real estate is exempted from the income tax because it is already taxed as property, then personalty must be also exempted, because it is similarly liable to the property tax. The income tax would then become a special tax on labor, thus involving the very opposite of the modern demand to treat "unearned" incomes more severely. But even where personalty escapes taxation or where the general property tax has become in practise, as in New York, or by law, as in Great Britain, a local tax on real estate alone, the situation is the same. In both cases it has lost its character as a personal tax and is now a semipersonal tax, called a tax in rem in the one case or rates in the other, just as the land tax has become an *Ertragssteuer* in

Germany or an *impôt réel* in France. It is for this reason that New York follows the system of including in the state personal income tax the yield of real estate subject to a local tax in rem, just as it includes the income from dividends on securities subject to a similar (business) tax in rem. To demand in New York the exemption of land would today appear almost as strange as would a similar demand in Great Britain. In Great Britain, in fact, such a demand never arose, because by the time that the first income tax was imposed rates had already for generations been a local tax on the occupier. The fact that the demand is still found in some American states testifies to the confusion that still prevails as to the distinction between personal and semipersonal taxes and as to the incidence of taxes on land compared with those on capital.

In countries where both the general property tax and general income tax apply demands have been made to allow for the general property tax in assessing the income tax. It is clear that if the general property tax is really enforced, the simultaneous taxation of both property and income involves an additional tax on incomes from property as compared with other incomes. The solution of the problem depends therefore on the intent of the legislation. If this is the avowed object of the fiscal system, the simultaneous taxation of the property and income becomes, as in Germany, a simple way of effecting the differentiation of taxation, i.e. the higher taxation of unearned income. The seeming inequality is thus merged into a higher equality. When this object, however, is not sought, there is occasionally found, as in some of the Swiss cantons or as formerly in Massachusetts, an allowance made in the income tax for the income from property already liable to the general property tax. Such a device is, however, suitable primarily to conditions under which, as formerly in Massachusetts, the income tax is an insignificant supplement to the all embracing general property tax.

Finally, there is the problem of allowing for the income tax in assessing the general property tax. This problem arises in cases where the income tax has begun to assume some significance, but where the general property tax is still the more important. In some of the American commonwealths the amount of the income tax may be set off against the assessment of the property tax. This disposition of the matter, however, is open to serious criticism. In the first place, it still subordinates income to property as the criterion of taxable ability, whereas the modern tendency

is quite the reverse. Secondly, by permitting the deduction of non-property incomes from property incomes it frustrates one of the chief objects of the modern income tax, which is precisely to reach non-property incomes. Thirdly, it retards the development of the property tax from a personal to a semipersonal tax—a development which is rapidly going on in many of the American commonwealths and which has been virtually consummated in New York as it has long since been accomplished in most of Europe. Under this development the general property tax has in practise or by law shrunk to a tax in rem on real estate (still supplemented in a few American commonwealths by a similar tax in rem on certain forms of tangible personalty). In such cases the personal tax has disappeared, requiring the reimposition of a personal tax through an income tax. For these reasons it seems inadvisable to make allowance for the income tax in assessing the general property tax. It is far better to treat them as separate constituents of the fiscal system, to consider the income tax as the personal tax par excellence and to regard the property tax as a transition from the old personal tax on wealth in general to the modern semipersonal tax on the specific form of wealth embodied in real estate.

The Incidence and Effects of the Income Tax. The rapid extension of income taxes in modern times has focused general attention on the economic and social effects of income taxation. As in all other taxes, a distinction should be drawn between the incidence and the ultimate effects of the tax.

Income is derived from rents, wages or profits. Since economic rent is a pure surplus, a tax on rent as a constituent of a general income tax cannot be shifted. A tax on wages can normally be shifted to profits only if wages are at the minimum of subsistence. Since, however, all modern income taxes allow for the exemption of the minimum, a tax on wages, salaries or professional earnings is difficult to shift.

More controversial is the problem of incidence on profits. Under the older theory, still often held by business men, profits, like interest, are a normal part of cost, so that a tax on profits will be shifted through an addition to price. Under the newer theory profits, at all events as distinct from interest, constitute a residual income, and prices tend to be fixed at the point of marginal cost; that is, the cost of the marginal producer who earns no profits. A tax on profits is therefore intramarginal and normally not sus-

ceptible of shifting. It is only in cases of a sellers' market that prices may for a time be above marginal cost, but even in such cases where there are marginal profits a tax on profits is still a tax not on the causes but on the result of price. An income tax is therefore in general not shiftable.

Quite different is the problem of the general effects. Every tax tends to engender a new equilibrium of economic forces. An income tax also may ultimately and indirectly affect prices either by leading to a readjustment of interest rates or by retarding the increase of production. An excessive income tax may accordingly interfere with a fall in industrial prices as well as with a rise of wages, thus standing directly athwart the interests of the consumer as well as of the laborer. Even if a general income tax cannot be shifted it may, if immoderate, disadvantageously affect the position of other classes besides the immediate taxpayer. On the other hand, if the rates are moderate and if the proceeds are not wasted or unwisely spent, the effects of an income tax are to be measured in the last instance by the general criterion of the relative desirability of public versus private expenditure.

In addition to these general economic effects the taxation of income gives rise to problems of wider social significance. Under modern conditions, with the system of exemptions and abatements, the income tax is paid by a very small part of the community. There thus emerge the social and political implications of a tax reaching only the few in a state controlled by the many. In this respect, however, the income tax is less vulnerable than the general property tax, which exempts the incomes of all those that have no property because they spend their entire earnings. And yet American experience with the property tax has not disclosed any extreme difficulties, apart from those inherent in the very nature of democracy. The breakdown of the general property tax is due to entirely different considerations. This particular danger of the income tax must therefore not be exaggerated.

An appraisal of the adequacy of income taxation involves the further question: does the income tax distribute the burden of taxation in accordance with the best test of equality, that of faculty or ability to pay? Strictly interpreted, it is clear that income does not afford a perfect criterion of faculty. This is apparent from the following contrast. A is a bachelor living in a small town, in perfect health, enjoying an ample inheritance and miserly in his habits. B, with the same income, is the father of a large family, in-

habiting a great city, in continual need of doctors, dependent on a precarious livelihood, generous and public spirited, talented and needing artistic diversion. Can it possibly be claimed that they have the same taxpaying ability? None the less, the more the theory of clear rather than net income is accepted, the nearer is the concept of faculty approached. Imperfect as it is, income is after all a better criterion than any other test of ability to pay.

While the redistribution of wealth must always be a secondary aim compared to the purely fiscal purpose of taxation, progressive income taxes possess the merit of counteracting the tendency toward a greater disparity of wealth. As a means to this end, however, the income tax is inferior to the inheritance tax; high rates on income may dampen the ardor of private enterprise. But under present day conditions there still seems to be ample margin in the higher reaches of the graduated scale for an application of the purposeful redistribution of wealth.

At the same time certain purely fiscal factors militate against the adoption of the income tax as a single tax or even as the only direct tax. In the first place the income tax is vulnerable in that it is especially exposed to the consequences of fluctuations in prosperity: in times of depression the proceeds fall sharply, just at the time when government expenditures are likely to increase because of the added demands of state aid for unemployment and the other consequences of depression. This objection may perhaps be removed by the inclusion of a system of reserve funds intended to equalize the returns, such as is recommended in the report of the Special State Tax Commission of New York in 1932. In the second place, even in times of prosperity income is not an ideal criterion of ability to pay, so that it needs to be rounded out by the other criteria of faculty. Thirdly, the fiscal relations of the individual to the government are not exhausted by the principle of ability, but need supplementing by the principle of benefits, which realizes itself in quite different forms of revenue. The income tax consequently can never be more than a constituent of a plural tax system.

INCREASING RETURNS is a term referring to an economic condition which might be better described as decreasing unit cost with increased output. This result may be due to a number of

different circumstances, which are too often confused. It may be produced by more adequate cultivation of the soil, especially that involving greater and better capital equipment; it may follow an increase in output connected with the utilization of hitherto unused capacity; it may reflect internal economies, which become available with an increase in the size of plant, or external economies connected with the increase in output of an industry in a given area without regard to the size of individual plants. The conception of internal economies may be extended to cover the economies of combination, horizontal or vertical; but these are usually regarded as separate facts.

Perhaps the earliest formulation of a principle of increasing returns was made by Quesnay in his essay on grains for the great *Encyclopédie* (reprinted in *Oeuvres économiques . . .*, ed. by A. Oncken, Frankfurt 1888, p. 193-229), in which he set forth the possibility of approximately trebling agricultural output by improved methods involving a doubling of outlay. The condition of French agriculture, starved for lack of capital, gave grounds for this claim. That similar conditions may still exist is evidenced by more recent agricultural reports indicating that the efficiency of the farm is frequently hampered by lack of adequate capital. Another form of increasing return is really implied in Adam Smith's familiar statement that the division of labor is limited by the extent of the market, which indicates clearly that a small output does not make possible as great efficiency as a larger one.

Senior emphasized the contrast between agriculture, subject to diminishing returns, and manufacturing, in which indefinite increase in output was possible, frequently with increasing returns. The contrast is superficial and in part misleading. Manufacturing like agriculture is in general subject to diminishing returns with an increase in any one factor or group of factors when the other factors remain constant; agriculture, on the other hand, is under certain circumstances subject to increased returns, as pointed out above. Increasing returns come, if at all, only when all the factors are free to increase as needed.

While increasing returns as well as diminishing returns are the result of a changing proportion of factors, decreasing unit cost is typically a function of size of the individual plant or of the industry as a whole. This was brought out by Marshall, who also established the distinction between internal and external economies, and it

was emphasized strongly by Davenport. Other aspects of decreasing cost with increasing output—such as the utilization of unused capacity and particularly the fact that certain costs are relatively constant while others vary approximately in proportion to output—have been brought out in studies of the economics of railway rates.

The various types of increasing returns are responsible for a varied array of different economic phenomena and problems. Where the economies of size and the wastes of competitive duplication are so decisive and continue so far that two competing establishments in one market are necessarily and obviously less economical than one, the result is a condition of "natural monopoly." In such cases reliance on competition is abandoned and direct regulation of service and prices is substituted. In the United States, where such regulation is complicated by constitutional safeguards to private property, such industries are given a special legal status as businesses "affected with a public interest" and so exposed to special forms of regulation; but the legal reasoning on which this classification is based runs in terms different from the economics of natural monopoly.

Another condition more common than that of complete monopoly is that in which a few large establishments are able to hold a dominating position in a trade, surrounded by smaller concerns over most of which they have differential advantages. In the United States especially the antitrust laws tend to prevent large concerns in this position from pushing their advantages to the point of absorbing or extinguishing their competitors. In such a situation, however, some of the smaller concerns actually have costs as low as or lower than the larger combinations, in which not all the productive units can be expected to attain the efficiency reached by the best. In general the costs of the smaller concerns show more variability than those of the larger, some showing high efficiency and others struggling to keep alive, a condition which is explained in part by the simple fact that relatively inefficient concerns do not grow to large size. The dominating concerns thus find themselves protected from the vicissitudes of business fortune, leaving the smaller marginal producers to bear the brunt of conjunctural fluctuations.

The economy of increased utilization of fixed quantities of productive factors has led to the discovery that increased sales at less than previous average costs may bring increased profits. This is the condition underlying dumping of

surplus products in foreign markets and price discrimination generally. Where competitors retaliate and the practise spreads to the whole market, the result may be a state of cut-throat competition in which selling price may be less than cost even for efficient producers. Such price wars have led to pools and other methods of controlling competition, including the informal control described by Marshall as a "sentiment against spoiling the market."

The economies of mass production and of standardization intimately connected with it are unquestionably one of the principal reasons for the high product per worker achieved in American industry as compared with that of other countries. American industry is enjoying not merely the advantages of pioneering in this direction; because the scale of production in many foreign countries is smaller, it is difficult or impossible for them to imitate advantageously the specific technical methods by which American efficiency has been attained.

The external economies of large scale production lead to the geographical concentration and localization of industry; such localization, however, is often difficult to distinguish from that due to the special advantages of particular locations for special varieties of production. Localization of industry gives rise to many advantages, the principal of which are those flowing from the development of auxiliary industries and easy access to a central supply of qualified labor. Advantages of this type afford a basis for the "infant industry" principle—one of the chief arguments for industrial protection.

INDEMNITY, MILITARY. The device of modern origin by which a conqueror recovers part or all of the costs involved in successful

military operations is known as a military indemnity. Imposed at the conclusion of a war, it is justified by the legal conception of damages collected for injury done. Since the beginning of the last century it has as a general rule been provided for and regulated by the terms of the various peace treaties. The comparative recency of its emergence and recognition is accounted for by the slowness with which the legal doctrine of indemnity became established and also by the long period necessary for the development of international trade and finance on a scale adequate for the transfer of relatively large sums of money.

Although such indemnities must be clearly distinguished from the usual forms of pillage and loot which accompany military conquest, their origins lie in that direction. During the 'Thirty Years' War conquering armies lived on the country; when they came to a prosperous town requisitions were made, which if not paid were followed by dire consequences. There were, however, a few examples of a tendency toward refinement of this process. The action of Gustavus Adolphus II in exacting from the captured city of Berlin a monthly subsidy for the support of his army anticipates in a rough way the modern indemnity; but because of its indifference to legal considerations it is more properly viewed as a variant of conventional tribute. Wallenstein by orderly and methodical requisitions couched in the form of law anticipated Napoleon's success in making "war support war." The German imperial army was given the "right" to free quarters, and this Wallenstein turned into a money making business by giving localities a choice of making a money contribution instead of furnishing quarters. No pretense was made that these contributions were indemnities, but the quasi-legal forms used in making requisitions were a definite improvement over the earlier practises of loot. The Treaty of Westphalia throws interesting light upon the evolution of the idea of indemnity. That the empire should make compensation in money payments does not seem to have occurred to the representatives of France and Sweden, dominated by the feudal idea that wealth was essentially land and that "satisfaction" should be in the form of annexed territory. The Swedish armies, however, were allowed to retain and collect the money payments they had levied upon the German cities; the gold and silver with which they filled their war chest is sometimes referred to loosely as a money indemnity, but the sums were insignificant in com-

parison with the territorial annexations. Such a situation tended to persist until banking operations became more highly developed, particularly after the establishment of central banks around the turn of the century.

Another marked stimulus to the development of money indemnities was mercantilism. The spread of this new political economy during the latter half of the seventeenth century shifted the emphasis of economic enterprise to the acquisition of gold and silver. The opinions of the rising mercantile interests in England, which since 1630 had become increasingly articulate, were reflected in Cromwell's exaction of one million guilders in the treaty of 1654 concluded at the end of the Dutch war. In keeping with the new economic theories imperialistic policies were formulated with an eye to securing "treasure" as well as land, and the European powers imposed contributions for the common defense upon their American colonies. These payments were sometimes referred to as indemnities, in the sense that they were compensation for the expenses which the mother country had incurred in protecting the colonies or in extending their territories by conquest. This was a fruitful source of controversy between Great Britain and her North American colonies after the peace of 1763; the attempt on the part of the British ministry to place part of the cost of the French war in North America upon the colonies brought on the bitter struggle over taxation which preceded the outbreak of the revolution.

The mercantilistic philosophy was important for the development of the practise of exacting an indemnity, not only because it emphasized the importance of payments in currency but also because it contributed to the making of the modern nationalistic state. In the process declarations of war became more formal, army organizations were regularized and gradually there evolved a new set of standards, incorporated eventually in a formal body of international law. The practises of pillage and loot were generally condemned; rights of private property were given increasing recognition and protection. The commanders of the new national armies were, in striking contrast to the independent personal jurisdiction of the earlier military leaders, under the direction of the king and his ministers; campaigns were guided strictly by the dictates of national policy and national ambition; and their new standing armies paid from the national treasuries and no longer dependent on loot and pillage showed greater respect for the rights of

private property in invaded territories. The national governments, now shouldering the entire financial burden of war, contemplated with growing interest the possibility of sharing this burden with the defeated power by the device of a military indemnity. The comparatively simple logical transition from the concept of private compensation to that of a bill of damages assessed against the enemy afforded a convenient solution. The right to exact such indemnities—the borrowed nomenclature acquiring a formal status—in general peace settlements became generally recognized.

As applied throughout the nineteenth century, however, military indemnity revealed marked deviation from the logic of its inception. Indemnity in law means compensation for damage suffered and involves the idea of justice, while military indemnity came to mean payments levied by the victorious power upon the defeated, the basis of the indemnity being military success, with little regard to the justice of the case. As Napoleon's armies advanced in the Jena campaign they levied in the manner of Wallenstein indemnities upon cities under threat of destruction. In cases where money could not be paid the conqueror took the bond of leading citizens, particularly bankers. By the Treaty of Tilsit, Prussia lost half her territory and had her population reduced to five millions. Upon this mutilated kingdom Napoleon imposed an indemnity of 154,500,000 francs, seized crownlands and insisted that contributions in default be paid, which brought the total to a sum estimated at \$130,000,000. This was an indemnity far beyond Prussia's capacity to pay, since the country was predominantly agricultural and had but a small volume of foreign trade. The emperor probably did not intend that it should be paid. By a convention signed at Königsberg on July 12, 1807, which supplemented the Treaty of Tilsit, Napoleon was given the right to maintain 100,000 men in Prussia at its expense until the indemnity was paid. He thus provided for the maintenance of a powerful force in Prussia, which was within striking distance of Austria and Russia. The convention is important in the development of the practise of keeping troops in the defeated country's territory pending the payment of an indemnity.

With the downfall of Napoleon no indemnity was imposed upon France by the first Treaty of Paris (1814), since the allies wished to make the position of Louis XVIII as secure as possible and since they contended also that Napoleon and not

the French people was at fault. But the return from Elba altered the situation. In the second Treaty of Paris (1815), while still wishing to make secure the position of the French sovereign, the allies insisted that responsibility for the Hundred Days rested with the French people and imposed an indemnity of 700,000,000 francs upon France, in addition to which it was to maintain at a cost of 250,000,000 francs a year an army of 150,000 men, who occupied its chief frontier fortresses for a period of five years.

The most famous indemnity of the nineteenth century was that imposed upon France by the Treaty of Frankfort in 1871—an indemnity which has often been criticized as introducing the punitive element. France was compelled to pay 5,000,000,000 francs and to support a German army in northern and eastern France until the indemnity was paid. Bismarck and the military party in Prussia thought that this would weaken France financially and keep a German force in France for years. To the surprise of the world the French paid this indemnity in little more than two years. In the payment of such a sum from one nation to another there are two problems. France solved the internal problem by the sale of bonds to her citizens, bonds which were still outstanding and an obligation of the French government when the World War broke out in 1914. The external, or transfer, problem was solved by turning over to the German government banknotes, securities that were acceptable and bills of exchange. The French government through the Bank of France was able to purchase in France about 750,000,000 francs' worth of German banknotes, 1,500,000,000 francs' worth of first rate securities, stocks and bonds with an international market, which the German government sold for marks in Berlin; and finally the remaining 2,750,000,000 francs was used to purchase bills of exchange, the usual method of making international payments, which meant that goods to this value were shipped out of France and the money thus earned turned over to the German government.

The comparative ease with which the French paid this indemnity showed how greatly such payments could be increased by the use of public credit and large scale banking operations. To have attempted to raise this money by taxation in so short a time would have aroused decisive opposition in France, but the sale of bonds to investors was a comparatively easy matter when to the appeal of a good safe investment was added the patriotic one of ridding the country of the

hated German soldiers. The transfer problem too was relatively simple. Even the fairly large payments made in drafts were facilitated by the fact that Germany was at that time a free trade country.

By the Treaty of Shimonoseki in 1895 Japan forced China to cede Formosa, the Pescadores islands and the Liaotung Peninsula, including Port Arthur. But Russia with its own eye upon Port Arthur and the Liaotung Peninsula insisted with support from France and Germany upon the return of this Manchurian territory to China, which by way of compensation added \$22,000,000 dollars to the original indemnity of \$158,000,000, bringing the total up to \$180,000,000, which China paid largely by the aid of European loans.

Before the World War a controversy arose over the economic effects of paying a large indemnity. In *The Great Illusion* (London 1910, 4th ed. 1913) Norman Angell took the position in a chapter on the indemnity futility that in our economically interdependent world the nation receiving a large indemnity would suffer from financial disturbance in the credit of the paying nation, and furthermore with governments adopting protectionist policies it was likely that the payment of a large indemnity would be hampered by raising tariffs against the goods of the paying country. Free traders admitted the disturbance to credit but at the same time were willing to accept the goods, since the payment of an indemnity meant not only the transfer of goods but of purchasing power as well. It was Angell's contention that France was better off in the seventies of last century than Germany, that French industry was stimulated by the payment of the indemnity, while German industry struggled with a severe unemployment problem in 1876-77. This was true enough, but how far the payment of the indemnity was an effective cause is difficult to say. It was a period of severe depression which affected other countries, notably the United States, as much as Germany. H. H. O'Farrell, in a penetrating study made for the Garton Foundation, disagreed with Angell on the specific point that Germany had derived no real benefit from the payment of the indemnity. He quoted with approval Serrigny's opinion that "it permitted Germany to effect a greatly needed monetary reform, and to increase during a long period its military power, without putting any serious strain on the masses of its population." But O'Farrell pointed out that success with an indemnity depended upon three things:

the defeated nation must be sufficiently rich, its defeat must be crushing and complete and the war of very short duration. All three advantages were with Germany in 1871 and with Japan in 1895. In the latter case it is usually conceded that the foreign credits which Japan secured aided in the movement toward the modernization of her industry, but it would be a great mistake to attribute the industrial advance of Japan or of Germany to the payment of indemnities.

By the time the World War ended the term indemnity had lost its original legal connotation and by liberals was classed with annexation as a method of securing loot. The demand for a peace based upon the principle of "no annexations, no indemnities" reflected the distrust associated with the historical use of the word. Therefore the peacemakers of Versailles decided upon the new term, reparations (*q.v.*). This was made to cover actual damage done, separation allowances and pensions. Germany protested vigorously against the last two categories, which she contended were not included in the Armistice agreement. The peace settlement provided for a Reparations Commission, which reported on April 27, 1921, that the total payments required of Germany amounted to 132,000,000,000 gold marks, a sum which obviously had no connection with Germany's ability to pay. The Dawes report changed this sum to an indefinite series of annuities starting at 1,000,000,000 gold marks and rising to 2,500,000,000 gold marks in the fifth, or standard, year. By the Young plan these payments were still further reduced to a definite, terminating series of fifty-nine annuities ranging from 1,641,600,000 gold marks in the first full year, 1930-31, to 2,352,700,000 gold marks in 1965-66, from which point they decline to 897,800,000 gold marks in the last year. The payments of the second year, 1931-32, have been suspended through the acceptance by the Allied Powers of the moratorium proposed by President Hoover, leaving the question of further payments uncertain and unsettled.

Since the period when it first began to engage the interest of eighteenth century statesmen the broad problem of military indemnity as involving two or more nations has frequently been intimately related to the more limited problem of the responsibility of the individual state to indemnify its citizens and communities for property losses suffered at the hands of an invading enemy. The payments from the French treasury in such cases have been designated aids, reliefs or assistances. A law of August 16, 1793, de-

clared in the name of the nation that "it would indemnify all citizens for all losses which they have sustained or may sustain in consequence of the invasion of the enemy." In 1816 the government paid a sum of 100,000,000 francs to the invaded departments as compensation for damage suffered. After the Franco-German War the French passed a law with the following provision: "Compensation will be accorded to all who have been subject, during the invasion, to contributions of war, requisitions, either in money or in kind, fines and material damages." The deputies wanted to use the word indemnity, to fix definitely the responsibility upon the state; but the government to avoid such responsibility wanted to use the word relief, and finally as a compromise the word compensation was agreed to. During the World War the French government constantly took the position that it would compensate the invaded districts as provided by the law of 1871 and added that in the peace settlement it would look to Germany for indemnity. Therefore the French position on compensation to individuals assumed great importance in the reparations question.

The German law and practise have been similar to the French. Austria appointed a commission in 1866 which appraised damage done in the invaded areas and granted adequate indemnity. In the following year Saxony was even more generous. In 1871 the German Empire gave complete indemnity to the people of Alsace-Lorraine on the ground that damage had been caused to their own people by the acts of their own army. This indemnity was paid out of the large indemnity exacted from France. The Germans went so far as to appoint a commission to fix the indemnity due to German shipowners for losses suffered in consequence of the war. The German government's generosity was not challenged, because the heavy indemnity exacted from France made it possible to indemnify German citizens liberally and yet not cause budget difficulties and increased taxation.

INDENTURE is one of the devices by which business enterprise or government action has transferred labor to new and developing countries. Like the maritime slave trade and the later system of contract labor, it has found its typical occasion in the presence of undeveloped resources awaiting exploitation; and its typical effect has been to meet the costs and overcome the human inertia that keep labor from flowing rapidly and automatically to such lands. Unlike slavery, however, servitude under indenture is neither lifelong nor hereditary but extends for a limited term of years on a basis which is, at least in form, contractual. On the other hand, it differs from the looser obligation of mere contract labor in that the indentured servant may be compelled to carry out his agreement by specific performance of the work itself. Characteristically also the relationship is attested by a formal document, the indenture; but many indented servants in America occupied that status without such papers and merely according to "the custom of the country."

The first major use of the system was in the British colonies in North America. Resources were abundant, population was scanty and wage earners were hard to hold on any terms in the face of opportunities for independence. Certain colonies offered headrights in land to those who paid immigrants' passages; and, more important, would be employers and particularly farmers and planters in the middle and southern

colonies, where cash crops could be raised, stood ready to pay considerable sums to secure a more permanent working force. On the other hand, there were in Europe, as Sir George Peckham had foreseen even before Jamestown was founded, great numbers of people living "in such penurie & want, as they could be contented to hazard their liues, and to serue one yeere for meat, drink and apparell only, without wages, in hope thereby to amend their estates." The difficulties of the Scotch in north Ireland, the ravaging of the German Palatinate and other special circumstances from time to time increased the supply; but "penurie" was sufficiently general to provide a steady stream of willing migrants, which came almost entirely from the British Isles during the seventeenth century but very largely from Germany in the eighteenth. Thousands of poor men and women were quite ready to bind themselves for longer than Sir George's "yeere" in return for the transportation which was otherwise beyond their reach; and others were willing to go as redemptioners, who hoped to find relatives or friends to pay their passage money after they reached America but if not agreed to serve.

The demand, however, outran even this great supply. Indentures could be sold at the American ports at prices which rose to more than twenty pounds per adult before the colonial period ended and were sufficient to make active recruiting profitable. A host of agents called *Neulanders* used the most extravagant methods of enticement in Germany and elsewhere. Others engaged in the organized trade of kidnaping unwary persons from the streets of the British cities, and the fear of these "spirits" left significant traces upon both the life and the fiction of the period. Ship captains sometimes found it possible and profitable to reduce immigrants who set out with full passage money to the status of servants. Even in America there was some local recruitment; indenture became an alternative to imprisonment for debt and other offenses and there were a few cases of voluntary submission to the status, usually on much better terms than those obtained by the transported servants. In the meantime British government authorities were using transportation to rid their country of numbers of paupers, political prisoners and common felons. In spite of colonial protests perhaps fifty thousand convicts were shipped under indenture to the mainland between 1717 and 1775 and many others to the British West Indies. It was by force and fraud then that many of the indentured immigrants

were brought into contact with the opportunities of the new country; but it seems clear that the voluntary entrants must nevertheless have been in the majority; and in these migrations there came not only peasants and agricultural laborers but also teachers and the more highly prized mechanics of a variety of trades.

Although they varied greatly the most common terms of service under voluntary indenture were four and five years with longer periods for children, while the convicts were usually "his Majesty's seven-year passengers." The master was under obligation to support the servant in sickness and health and to give him at the end of the term his "freedom dues," which in the absence of a definite agreement consisted typically of "apparell," an axe, two hoes and a year's supply of corn or in later years their money equivalents, and sometimes also fifty acres of land. The legal aspects of the relationship were largely worked out in Virginia, where formal indentures were in use as early as 1619. The master's claim was assignable without the servant's consent, and it became settled that the servant could not carry on trade or marry without the consent of the master and that the latter had the right to inflict "moderate corporal punishment." It became moreover the policy of the courts to punish, not merely by whipping but also by lengthening the term of service, such offenses against the master's time as running away or the bearing of children. This indeed was the chief bulwark of specific performance and the closest approach to the conditions of slavery. On the other hand, the magistrates made special provisions for hearing the servant's complaint against "immoderate correction" or breach of contract and occasionally went so far as to free a servant outright in such cases or arrange his sale to another master. As the influence of the freedmen increased and as the economic importance of indenture declined, greater provision was made for the protection of servants, including the ruling that contracts of indenture could not be assigned without the consent of the servant.

Within this general framework the human content of the relationship must have varied very widely. Ill treatment was particularly common during the voyage, and immigrants who did not speak English were easy prey to chicanery. The great number of runaways has been rightly taken as evidence of frequent abuses under indenture but may also suggest the presence of tempting alternatives. A condition which often involved working alongside the master in the fields and

occasionally ended in marriage into his family seems to have carried no great social stigma except where the indentured servant class came mainly from the convict group. Its terms approached those of apprenticeship, from which it developed, more closely than those of slavery, although applying to adults as well as to young persons; and many immigrants found it a useful although arduous way of learning the technique of American farming. After the term was up the former servant suffered no disabilities other than those common to poor persons attempting to make a start in a new country, and his chances depended less upon his previous condition than upon the availability of land for settlement. The careers of certain individuals have been traced from servitude to colonial prominence and even to Congress: on the other hand, it has been suggested that freed servants furnished more than their proportion of the poor whites of the south. It was, however, one of the most significant features of the American regime of indenture that those who passed through it became for the most part indistinguishable from the mass of the free population.

The importance of indenture in the development of the country may be suggested by the estimate that nearly half of the total white immigration to the thirteen colonies came over under this device. After the revolution, however, reliance upon it rapidly diminished. One result of the war itself was to divert the shipment of convicts to another continent and another system. Still earlier the abundant supply of Negro slaves had made indenture of slight importance in the lower south and in the tobacco colonies, to which they had at first been so essential. Even in Pennsylvania, where the system was of much more lasting significance, its traces disappeared shortly after 1830. Stricter regulations of conditions on shipboard and of the terms of servitude had reduced the profits of the trade, and an Indiana decision in 1821 had held indentures unenforceable under a state constitution based upon the Ordinance of 1787 prohibiting involuntary servitude in the Northwest Territory. The principal reason for the decay of the system, however, seems to have been the passing of the urgent economic need: employers with a larger supply of labor at hand no longer found it necessary to advance the costs of passage and commit themselves to long engagements. Business enterprise did not permanently abdicate its role in moving workers across the Atlantic, as is shown by the later history of contract labor and steam-

ship company solicitation; but indenture proper died an easy and a natural death in the United States long before the passage of the Thirteenth Amendment extended the prohibition of involuntary servitude to the whole country.

Just when the system was dying out in the United States, however, it was revived in the British sugar colonies after the abolition of slavery. The problem was similar. White planters had seen their opportunities for profit limited by the scantiness of the native population or by its reluctance to give up the independence of primitive economy, and when the Negro freedmen in large numbers chose to leave the plantations, the owners turned to the expedient of colonization by indenture. In later years the same method was employed in tropical agriculture in various regions and occasionally for other work and drew a greater variety of indentured migrants in larger numbers and to greater distances than in the North American case.

This time it was mainly the Asiatic peoples whose "penurie and want" furnished the source of labor supply. When Mauritius began in 1834 to import indentured coolies from India, it tapped a stream of migration that was to carry a total of some 450,000 Indians to that one small island, over 200,000 to British Guiana, about 150,000 to Trinidad and smaller contingents to Jamaica and others of the British West Indies and that was chiefly responsible for an Indian population in Natal which long exceeded the white and now numbers about 150,000. It also provided substantial bodies of laborers for Réunion and other French colonies during the mid-century and for Dutch Guiana after 1872, and still later it sent thousands more across the Pacific to Fiji. Indenture moreover was one of the devices used in the large movements to the tea plantations within India and to nearby Malaysia. Meanwhile the Chinese, who became the second great source of supply, had long been migrating to neighboring regions, often under a system of debt bondage that somewhat resembled indenture and was later assimilated to it in the legislation of British Malaysia. Occidental exploitation of this opportunity did not begin until the 1840's but proceeded very rapidly. It is claimed that between a quarter and a half million Chinese were carried under indenture to Cuba, Peru, Chile and Hawaii in the years 1847 to 1874. The movement to Hawaii continued throughout the century, reaching a total of about 35,000; and from 1853 on some 16,000 were taken to British Guiana. The gold

mines of the Transvaal employed nearly 50,000 from 1904 to 1907; three times as many were used in France and Belgium during the World War; and since that time indenture has supplied small numbers of workers to the former German islands of Western Samoa and Nauru. Nor does this complete the list of strange transplantations. To Australia, which had already experimented with both white men and coolies under indenture, nearly 60,000 South Sea Islanders were carried for work in the Queensland sugar fields; Javanese laborers have served under the system in both the East and the West Indies; and about 65,000 Japanese and over 10,000 Portuguese and small groups of Germans and Scandinavians were brought to Hawaii from opposite ends of the earth.

The more sinister features of the indenture were in these cases often intensified. Chinese "crimps" in the "pig" markets of Canton and Macao repeated with variations the worst practices of London "spirits," and the "blackbirding" of the Kanakas must have been virtual piracy. Early voyages from China duplicated the horrors of the "Middle Passage"; "the evil reputation of the coolie trade" was "well-earned in Cuba and in the Chincha Islands"; and the death rate of the Kanakas in Queensland was extraordinarily high. Even in the better regulated cases the vast racial differences must inevitably have produced innumerable instances of misunderstanding and abuse. On the whole, however, the terms of the contracts seem to have been more favorable to the laborers than under the earlier American regime, and there was far more governmental and intergovernmental action in their behalf. The commonest period of service in British territory was five years, but wages rather than mere subsistence were almost invariably stipulated; hours, tasks and housing were commonly regulated and flogging forbidden; and in some cases it was made possible for the worker to buy redemption before the end of his term. Government "protectors of immigrants" or similar officials were given considerable power and seem to have had real effect under British, Dutch and Hawaiian rule; recruiting in India and transportation from it became an enterprise of colonial governments rather than a private exploitation, and the Indian authorities more than once used the power to withhold the supply for enforcing better treatment in the country of destination. A crucial point was the fate of the laborer after the expiration of the indenture. Cuban regulations in 1860

forbade his employment in free occupations and gave him no assistance for the return voyage; the effect was to enforce reindenture and lifelong servitude. On the other hand, where repatriation was the general practise or was made compulsory, as in the Transvaal, the system involved the sexual difficulties and deprivations of an overwhelmingly masculine population. The Sanderson Committee in 1910 declared its opposition to emigration under indenture in cases where repatriation was required or to colonies which did not possess agricultural land available for settlement. But where opportunities in free occupations have been open after indenture, the result has frequently been the establishment of permanent settlements of colonists much less poverty stricken than their fellows in the home country. The immigrants have prospered in Hawaii; their occupation of the land has been particularly notable in the Guianas and elsewhere; and it was in part the economic success of the Indians in Natal that led to the restrictions against which Gandhi campaigned.

The termination of these systems has more often been a matter of government action than of mere economic decay. In Hawaii it followed automatically from annexation to the United States; in Australia and the Transvaal it was action taken largely in the interests of the competing white population; but more frequently—as in the 1870's when Chinese treaties checked the trade to Peru and Cuba or in the 1890's when India prohibited emigration to the French colonies—the motive has arisen from the treatment of the migrants themselves. When the system of Chinese indentured labor was abolished in British Malaysia between 1914 and 1916 and emigration under indenture from India was prohibited in 1917, the permanent use of indentured labor on any large scale came to an end. This device then has long since lost its function in the temperate regions and has today been virtually abandoned even for tropical colonization. At least in the latter case, however, spontaneous migration can hardly be counted upon to transfer labor from points of redundancy to points of need. Thus the problem which indenture was employed to meet remains a difficult question for international organization.

INDEPENDENT LABOR PARTIES. *See* SOCIALIST PARTIES; LABOR PARTIES.

INDEPENDENT VOTING is contrasted with party voting, but there are many marginal cases in which classification is difficult. Voters may reject party affiliation entirely because of ideas of civic duty, but independence generally arises from immediate issues or conditions or from a belief in causes which are placed above party adherence. There are probably few persons who are sustained eclectics in voting, yet most voters are no doubt independent occasionally. In practical politics the factor of interest is not the temperamental inclinations of individual voters, but actual instability in party affiliation in given electoral districts and upon specific issues. Thus in American presidential elections there is an extensive independence in "doubtful states."

Independent voting must be viewed in relation to the circumstances of an election. Periodic popular revolts against the traditional political organizations, or "machines," in American cit-

ies, as, for example, against Tammany, may indicate a temporary independence. If the overthrow of an organization is a result of the participation of a habitually inactive electorate, it is not, properly speaking, independent voting. Independent voters must in the first place be voters, although independence by temperament may be reflected in many cases in non-voting. Non-partisan municipal elections were advocated historically on the basis of the independent spirit; but mere participation in such an election, in which all voting is legally independent of parties, does not constitute independent voting.

The independent attitude in politics may be either organized or unorganized. The individual independent is not a threat to the party system, since the unorganized independent vote is divided between competing party organizations. On the other hand, an effective and relatively permanent organization of independents may become a political party. Whether organized independency, so-called, which offers a "Good Government" or "Citizen's League" ticket in a local election, is a local party or is simply organized independency presents a marginal case of some difficulty. Subjectively, it is probably independence, since the voters in the association regard it merely as a means of combating a temporary evil in local government while retaining their party adherence in state and national elections. More objectively, it is probably independence, since such associations have little organization in the party sense and such organization as they do have is temporary and rudimentary.

The organization of independency need not be exclusively against the party. The protest against "bossism" may assume the character of independency even in a non-partisan electoral district if a number of voters normally supporting the organization or organizations controlling local politics rebel and establish an independent organization. On such occasions the organized protest also hopes to draw to the polls a considerable percentage of non-voters. Independency may be solely in favor of a particular cause, such as the abolition of slavery, the enactment of "dry" legislation or progressivism. Organizations not essentially political in their functioning, such as the American Federation of Labor, may adopt political independence to secure political measures auxiliary to their principal activities. All such organizations must constantly weigh the candidates and platforms of the different parties; the American Federation of Labor, for example, maintains an elaborate record system

for this purpose. Such organizations must also weigh the desirability of organizing their own more or less permanent local and even national parties.

Representative democracy implies the existence of political parties, since in order to function the electorate must have leadership acting through organization. The traditional theory of democracy asserts that the elector in order to be effective must support some political party. In this view independency is an unexpected tendency in democracy, just as is non-voting, although both are perhaps inevitable. Independency is to be associated frequently with abnormal conditions in politics. In national, state and local elections it is accentuated during periods of corruption and party irresponsibility, although in national and state elections sustained independency or instability in party affiliation probably indicates a transition in party life or a new party equilibrium rather than independent voting. As long as party lines are distinct, independency is clear in the oscillation of the political pendulum; but if the instability becomes so great that party organization deteriorates, as in the American "era of good feeling," it can hardly be called independency, which is ordinarily of a temporary or a specialized character. A new political party is based on the willingness of voters to shift their allegiance in the face of new issues, and its lack of tradition makes it subject to heavy political reversals, such as the British Labour party experienced in 1931.

Under the present one-party system of Russia, Italy and China, for example, independency must be reflected primarily in abstention from political life. In the American two-party system in national politics, where the parties are in large measure national federations of state organizations, independency is singularly ineffective, except in "doubtful states" and when there is important "bolting" from the party, such as the Progressive movement of 1912 and the La Follette movement of 1924. The Democratic and Republican organizations are traditionally strong. The position of the Democrats as a minority party means that its victories are based on a temporary drift in support of normally Republican voters. American minor or third party movements constitute a type of affiliation in which issues alone are important, but because of the character and relative permanence of their organization they are not independent but party movements. The multiparty system of most European and parliamentary countries blunts

the clarity and traditional stability of party differentiation, making a transfer of allegiance easy. Under the multiparty system independency less organized and less extensive than in the United States can hope to influence the parliamentary situation; but it is also much more difficult to recognize. In normal times in the United States independency is little in evidence in national elections, and it is widespread only on issues which arouse the deeper convictions and antagonisms of the electorate. In the latter case so many non-voters participate in elections that it is difficult to estimate the force of independency.

The adoption of the direct primary for the nomination of state officers, the presidential preference primary, the initiative, referendum and recall, non-partisan local and judicial elections and emphasis on the conception of public administration as the management of public business, as in the city manager movement, have in their totality been an important stimulus to independency. Defenders of the direct primary, especially the "open primary," and of non-partisan elections believed that the regime of the party would be brought to an end by these reforms. National elections have been little influenced by independency as a result of these measures; and in states predominantly Democratic or Republican, where a one-party system has existed in fact, it may be doubted whether an effective independency has been created by regulation and alteration of the party system. The non-partisan ballot in a predominantly Republican city election, for instance, may do little more than eliminate any clear consciousness of the party.

The defense of independency in politics is finally simply a plea for a spirit of public criticism on the part of the voters. Reformers have argued that progress in government can come only with a citizenship capable and willing to judge party candidates and platforms independently and without prejudice. They have felt that the historic parties are essentially organizations rather than "brokers" of candidates and issues, as A. L. Lowell spoke of them. The party adherent in reply has pointed to the futility of independency and asserted that active participation in politics through the party will attain much more in the elevation of politics than will a repudiation of party regularity.

INDETERMINATE SENTENCE. A definite sentence of imprisonment pronounced by a court at the conclusion of a criminal trial fixes within the limits set by the law the exact number of days, months and years which the convicted offender must serve as punishment for his offense. By contrast the indeterminate sentence—or the indefinite sentence as it has been called also, although neither term is adequately descriptive—does not specifically designate the length of imprisonment. Usually the court names minimum or maximum limits or both, but occasionally it merely commits the prisoner to an institution, the time limits mentioned being specified by laws governing the administration of such institutions or of parole. The actual time of release is in such cases usually determined by administrative agencies.

The indeterminate sentence originated as a means of securing social protection against habitual offenders; it was occasionally used in the Middle Ages and seems to have been introduced for this purpose into the *Carolina* (1532), the *Theresiana* (1768), the colonial laws of Connecticut (1769) and the Prussian *Landrecht* (1794). In some of these laws it appears in connection with primary penalties, but in Prussia it was used for the preventive detention of certain dangerous offenders who had completed a fixed penalty for certain specific crimes. In the Prussian decree of 1799 it was employed as a primary penalty for thieves and robbers; in Feuerbach's monumental achievement, the criminal code of Bavaria (1813), and in the code of Oldenburg (1814) patterned upon it the use of the indeterminate sentence was extended to a number of other offenders under very long terms of imprisonment. It is not known how far it was employed elsewhere on the continent; but the courts of Spain and its West Indian colonies must have used it, since royal decrees of 1772 and 1786 prohibited it. By the middle of the nineteenth century it had disappeared, however, even from German criminal law, where it had survived longest.

Some of these early laws appear to have had not only preventive but also reformatory aims. The Prussian decree of 1799 specifically prescribed detention until the prisoner showed signs of reformation or until he could pursue an honest trade. Article 12 of the Bavarian code stated that under sentences of imprisonment for an indeterminate time the prisoner retained the opportunity of earning his liberty through actively expressed reformation. When indeterminate confinement for minors appeared in connec-

tion with juvenile reformation—as in the House of Refuge of New York City in 1824—the reformatory aim of this type of sentence was clearly shown.

The extension of the indeterminate sentence to adults for corrective purposes received its greatest impetus in the United States, although legal and social philosophers and medical scientists in many countries prepared the way for its acceptance. These men realized that automatic and uniform penalties failed to take into account the individual differences among prisoners and could not utilize the incentives to reformation found in a device which places in the prisoner's power some means of shortening the duration of his confinement. A number of such devices were put into practise during the nineteenth century (see **COMMUTATION OF SENTENCE**). Inspired by the theoretical validity and the practical success of these devices, the prison reformers of the United States during the middle of the last century began under the leadership of E. C. Wines, Louis Dwight and Zebulon Reed Brockway an agitation for an indeterminate sentence which would permit a better individualization of prison treatment. In his paper before the National Congress of Penitentiary and Reformatory Discipline in 1870 on "The Ideal of a True Prison System for a State" Brockway stated that criminals should be treated "in such a manner that they shall either be cured, or kept under such continued custodial restraint as gives guarantee of safety from further depredations." He furthermore proposed that "all persons in a state who are convicted of crimes or offenses before a competent court shall be deemed wards of the state, and shall be committed to the custody of the board of guardians of penal and charitable institutions until in their judgment they may be returned to society with ordinary safety and in accord with their own highest welfare." This idea he embodied in part in the Michigan law of 1869, later declared unconstitutional, which governed the commitment of certain offenders to the Detroit Home of Correction. He wrote it into the bill which he drafted in 1877 governing the administration of the then recently established Elmira Reformatory in New York. The New York legislature refused, however, to accept an indeterminate sentence without time limits and compromised by adopting a sentence with a maximum penalty as already prescribed in the penal code of the state for specific offenses. In 1889 New York extended the indeterminate sentence to state prisons; and although other states

were at first reluctant to follow this example, the twentieth century saw a rapid growth in such legislation. Thirty-six states now carry indeterminate sentences in their statutes with little uniformity in their form and application. Life prisoners; recidivists; criminals above a certain age; or those convicted of certain types of crime, such as murder, treason, arson and rape, are frequently excluded from the operation of the indeterminate sentence laws, which are on the whole reserved for first offenders or for those who have committed less serious crimes. The indeterminate sentence is rarely applied in cases of misdemeanants—it was, however, so applied in New York in a statute passed in 1915—and its use in connection with more serious offenders is increasing. In 1928 of a total of 48,212 persons admitted to state prisons and reformatories, whose time sentences are known, 26,555 were received under indeterminate sentences.

There has been a great deal of opposition to the indeterminate sentence. It has been claimed that it violates the public's sense of justice, which demands that penalties should be measured by the gravity of the offense; that it violates the civil right of the citizen to know definitely when his punishment must cease; that it transfers judicial power to administrative agencies. It has also been asserted that although the indeterminate sentence may under ideal conditions be valuable it presupposes the existence of successful methods of reformation in institutions and proper facilities for parole supervision and that neither has yet been properly demonstrated. The constitutionality of these laws has not been successfully challenged, nor have American legislatures so jealously guarded the prerogatives of the judiciary as have some other countries. The advocates of the indeterminate sentence have contended that scientific penology makes it necessary; that proper individualization of prison treatment and organized supervision on release in the form of parole require it; and that its deterrent power is at least equal to that of definite sentences. The extremists among them believe that the goal to be sought is an absolutely indeterminate sentence which would completely transfer the power of determining even relatively the time of release from the trial court to some other agency, preferably administrative in nature.

The purpose of the indeterminate sentence has frequently been practically nullified either by the courts or by those who have administered its execution. In many jurisdictions where the

former have been able to exercise discretion in its use the minimum has sometimes been fixed either close to the maximum or made identical with it, reducing the law to a fiction. Prison or parole administrators have frequently been unable or unwilling to accept the implications of the sentence. In many states the prisoner's release at the expiration of the minimum time has been almost automatic; only in a few states have provisions been made for adequate parole supervision, which has commonly come to be regarded as a necessary adjunct to the law. In spite of this fact, however, the average length of time served under indeterminate sentences appears from almost all state studies to be greater than it was under the preceding definite sentences.

In recent decades the indeterminate sentence has reappeared in the criminal law of continental countries and elsewhere; it was adopted by Norway in 1902, by New South Wales in 1904, by New Zealand in 1905 and by England in 1908. These enactments are comparable in type to those in the United States but were adopted as "measures of safety" against habitual and dangerous criminals. Spain and Sweden in 1928, Yugoslavia in 1929 and Denmark in 1930 added similar preventive detention laws. Austria in 1928 and Denmark in 1930 also extended the indeterminate sentence to juvenile or adolescent delinquents for corrective purposes, a reform likewise included in the German penal code project. A number of European legal and penological authorities have become strong adherents of the principle; in 1910 and 1925 the International Prison Congress officially adopted it by resolution.

INDEX NUMBERS

PRICE INDEX NUMBERS. *History.* In its broad and generic meaning an index number is an average of relatives or variations. If the variations measured are those of commodity prices, an index number of prices is obtained; index numbers of wages, interest rates, profits, production and of a large number of other measurable phenomena have also been computed. Each of the applications of index numbers may be subject to peculiarities of its own; and in every case the average is drawn for a certain purpose for which it should be appropriate. Index numbers were first used to measure the rise or fall of prices, i.e. the inverse movement of the general exchange value of money; and the term itself was coined in this connection. In 1838 Porter used the term index prices, and in 1869 the London *Economist* called the sum of relatives of twenty-two prices which it compiled the total index number. Jevons took over the term index number and it quickly came into general use. It was incorporated into most foreign languages to denote either the prices of individual commodities averaged at each period or their total sum or an average of them, the last meaning gradually coming to be the most common. Axiometry, the measurement of the general exchange value of money, is the most important field in which index numbers can be used; it should not be merged and lost in the wider study of index numbers. In this section attention will be confined to axiometry.

Since money is used as the measure of the exchange value of other commodities and as the standard of deferred payments it ought to be stable in value. All "weights and measures" must themselves be measured in order to be kept stable. Money needs this most of all, since it is a notoriously unstable measure and misleading unless its own variations can be allowed for. The measurement of the changes in the value of money began early in the eighteenth century after a long continued rise of prices. Previously

there had been only desultory estimates, as, for example, those of Bodin. Locke and other early writers would have compared money with a single commodity, the commonest food, as being more stable over long periods of time and therefore better serviceable as a standard. Later it came to be more or less consciously perceived that all commodities cannot either rise or fall in their mutual exchange values and that therefore all commodities constitute the standard; in default of all, many preferably to a few, and a few preferably to any one. At first only a few were used, and since then one line of progress has been the extension of the number.

The earliest systematic use of several prices is to be found in Fleetwood's *Chronicon preciosum* (London 1707); his work was rough, as he found all his prices to have risen nearly alike. Soon it was found that prices had risen unequally and needed to be averaged. The arithmetic average was used as a matter of course. Dutot in *Réflexions politiques sur les finances et le commerce* (2 vols., The Hague 1738; vol. i, p. 365-77) simply averaged prices as quoted, which meant haphazard weighting. Carli in 1764 employed even weighting by calculating percentages of the price variations and averaging these (*Scrittori classici italiani di economia politica*, vol. xiii, Milan 1804, p. 299-366). Evelyn (in Royal Society of London, *Philosophical Transactions*, 1798, pt. i, p. 133-82), attempting to measure "the depreciation of money," modified this method by multiplying the results by 100 and, lumping together several less important articles, invented a rough weighting by classification. Arthur Young in *An Enquiry into the Progressive Value of Money in England . . .* (London 1812, p. 66-135) improved upon the weighting by counting the more important articles several times. Lowe (*The Present State of England . . .*, London 1822), writing at a time when prices were falling, recommended listing the quantities of many commodities consumed by the people (the estimates to be changed every five years) and setting down their prices from year to year, so that changes in the total sums spent on them might indicate inverse changes in the "power of money in purchase." His scheme was called the tabular standard by Scrope. (*Principles of Political Economy . . .*, London 1833, p. 405-08), who followed him in wishing to measure the variations that occur in "the general exchangeable value" of money. In 1859 Newmarch originated the useless practise, since become not uncommon, of starting from a plural base of prices

averaged over several years. In 1864 the *Economist* commenced an annual review of prices, comparing them with Newmarch's base (1845-50), and in 1869 began to add up the prices of twenty-two articles for comparison with their total price of 2200 at the base. Jevons in a pamphlet on *A Serious Fall in the Value of Gold* . . . (London 1863) and in an article in the *Journal* of the Statistical Society of London (vol. xxviii, 1865, p. 294-320) opened the theory of the subject. He set the problem of determining the preponderance of opposite variations but did not solve it, being misled by some false analogies, which caused him to neglect weighting. He adopted the geometric average and alluded to the harmonic, while Laspeyres (in *Jahrbücher für Nationalökonomie und Statistik*, vol. iii, 1864, p. 81-118, and vol. xvi, 1871, p. 296-314) defended the arithmetic. The controversy between them was futile because, paying insufficient attention to weighting, they unwittingly used different kinds. Yet Laspeyres admitted the propriety of uneven weighting and suggested using the weights of the base period. Paasche in a study of price movements published in the same magazine (vol. xxiii, 1874, p. 168-78) used the weights of the later periods. Meanwhile Drobisch (in *Königlich-sächsische Gesellschaft der Wissenschaften, Mathematisch-physische Klasse, Berichte über die Verhandlungen*, vol. xxiii, 1871, p. 25-48; and in *Jahrbücher für Nationalökonomie und Statistik*, vol. xvi, 1871, p. 143-56, 416-27) advised using both and thereby introduced double weighting. Later Messedaglia (in *Archivio di statistica*, vol. v, 1880, p. 177-224, 489-528) treated of averages in connection with this subject and recommended the harmonic.

Two lines of development may be traced through the further epochs of falling prices after 1873 and of rising prices after 1896. On the one hand, practical workers not only made more thorough investigations concerning prices in the past but undertook systematic measurements of price variations as they occurred from year to year; annually and at even more frequent intervals they published index numbers in statistical journals, following the example of the *Economist*. The making of index numbers spread from country to country and has finally been taken over by governments. On the other hand, theoretical workers have continued to probe into the theory of the subject with a view to improving the methods in use. In 1887 the British Association for the Advancement of Science appointed a committee to investigate "the best methods of

ascertaining and measuring variations in the value of the monetary standard." The secretary of the committee, Edgeworth, did most of the work on its several reports and appended to them three important memoranda (1888-90). Hitherto most writers had treated of methods only incidentally, rarely according them more than a page or two, although Drobisch, Messedaglia, Lehr and Walras gave them somewhat more attention. Edgeworth's memoranda were the first treatises devoted to the general methodology of the subject, but unfortunately he obscured it by bringing in extraneous matter. He took advantage of the ambiguity of the term "value" to extend the inquiry to the methods of measuring values other than exchange value, despite the obvious consideration that any question as to the kind of value in which money ought to be stable should form a distinct investigation. Edgeworth also set up various *quaesita*, asserting that "for different purposes different formulae are appropriate." Since then attention of research students has been divided between formulae for "measuring prices," for indicating "the trend" or "drift of prices," for "correcting the instability of trade," for serving as a "barometer of business" and the like. One of Edgeworth's aims was to solve the purely mathematical question of finding on the analogy of errors of observation the price variation from which the actual price variations least depart; to this end he recommended the geometric average with weighting inversely proportional to the size of the variations, here adopting a casual suggestion put forth by Jevons. Since for this purpose the quasi-average, called the median, as well as the mode is also suitable, he introduced them in axiometry; after much wasted discussion they have at last been abandoned.

Progress in the right direction was made by Westergaard (*Die Grundzüge der Theorie der Statistik*, Jena 1890, p. 218-20), who noticed that the simple geometric average had the merit, not possessed by the other simple averages, of making exactly the same measurement between distant periods directly or indirectly through intervening periods. Thus he set up for the first time a condition which formulae ought to fulfil and a criterion or test of a good formula. In 1901 Walsh published *The Measurement of General Exchange-Value* (New York), in which after distinguishing the various kinds of value he examined the nature of exchange value and the nature of averages applied to variations, with the aim of solving the problem regarding the preponderance of opposite variations left unsolved

by Jevons. He discovered several conditions or tests and modified Westergaard's into the circular test. The final result was the demonstration that several formulae are very accurate, although none is perfect. Somewhat later Fisher in *The Purchasing Power of Money* (New York 1911, 2nd ed. 1920) emphasized the correlation of price indices and quantity indices and the consequent fact that every price index can have an antithetical form, except certain ones which are their own antitheses. He also classified and named the tests, doubling them by applying them also to the quantities; among them he included the circular test, but later he abandoned it at least in theory and introduced a new one. In a later work, *The Making of Index Numbers* (New York 1922), he investigated in a somewhat mechanical manner all possible kinds of index numbers, formulating more than a hundred. He recommended one of the price indices which are their own antitheses as the best, calling it "the ideal index number," a name by which it is now generally known. More recently W. I. King in *Index Numbers Elucidated* (New York 1930) rejected all the principal tests and then used the circular test (p. 89, 94).

Theory. The immediate object of general price index numbers is the measurement of the general exchange value of money, or its general purchasing power. Money has a particular exchange value in each of the things exchanged for it, and this varies proportionally with the amount obtained and therefore in inverse proportion to the price. General exchange value is a composite of all particular exchange values. If all the particular exchange values of money remain constant (all prices unchanged) or if all vary alike (all prices inversely), the general exchange value of money remains constant or varies to like extent. If one particular exchange value falls, the general exchange value falls but not to the same degree; and vice versa in the case of a rise. If one exchange value of money falls and another rises at the same time, these opposite variations may compensate each other and money remain stable in general exchange value. If many fall and many rise, the one set may preponderate over the other or it may not. Jevons confessed that "the exact mode in which preponderance of rising or falling prices is to be determined is involved in doubt." This is the problem which Jevons failed to solve because he neglected weighting. It still calls for solution.

The problem of general exchange value index

numbers is preeminently that of averaging and weighting price variations. A price variation is a ratio and can be represented by a fraction, such as p_1/p_0 , where p_1 is the price in the current period and p_0 the price in the base period. Averages are functions of several magnitudes that lie not above the greatest nor below the least. When dealing with only two magnitudes, they are properly called means. Their formulae are subject to these conditions: (i) if all the magnitudes are equal, the average must be equal to them; (ii) if a magnitude equal to the average is added or withdrawn, the average must be unaffected; (iii) if a magnitude unequal to the average is added or withdrawn, the average must change. The arithmetic is the highest of the three classic averages, the harmonic the lowest. The geometric mean of two unequal magnitudes is the geometric mean of the arithmetic and harmonic means of the same; but the geometric average of three or more unequal magnitudes is not the geometric mean of the arithmetic and harmonic averages of the same, although when the magnitudes are numerous and not very divergent—and with price variations this is usually the case—their geometric average is then always very close to the geometric mean of their arithmetic and harmonic averages. If two or more of the magnitudes averaged are equal, the expression can be reduced and then the average is said to be weighted, the weights being the repetitions of the individual equal magnitudes. There is really no unweighted average, since the magnitudes must have at least the weights of one; the difference is only between evenly and unevenly weighted averages.

Of all the averages the geometric seems best suited to the measurement of price variations. Prices can rise more than 100 percent but cannot fall more than 100 percent. Obviously a rise of 100 percent is much less than a fall of 100 percent; rather it is equivalent to a fall of 50 percent, for the doubling of one price is counterbalanced by the halving of another, provided the two are prices of articles of equal importance over both the periods compared. The mean which indicates this is the geometric. But when two articles of unequal importance or more than two even of equal importance are involved, the rise and fall of prices may not compensate with absolute accuracy according to the geometric average, although in ordinary cases the geometric properly weighted makes a close approximation.

The next problem is that of proper weighting. A commodity which forms one item in a list of

price variations is simply one name for many units of the same commodity, and the price variation connected with it is not a single magnitude among the price variations listed. The only proper unit in axiometry is an exchange value unit, say a dollar's worth. Therefore price variations should be weighted according to these units which the commodities contain; that is, according to their relative values, which are unaffected by the physical units employed. For if p represents the price, q the quantity of the physical unit and v the value of the commodity, then $v = qp$ and a change of the physical unit merely makes p and q change inversely. Commodities are considered important according to their values; hence the common statement that weights should be according to the relative importance of the commodities. There is, however, a difficulty about the weighting of price variations because of the fact that two periods are compared each with its own relative weights, although it is neither the commodities nor their prices but their price variations that are the magnitudes to be weighted. Evidently the weights at either of the two periods compared are no better than those at the other, and of course no others come into question. Therefore, as criterion IV, the weighting of both periods should be used and of these only.

Another test springing from the nature of the subject, criterion V, is that changes of the physical units must not affect the result, since such changes affect neither the variations nor the values (weights). Prices and quantities are factors of the values. Therefore Fisher, who discovered the next criterion, VI, called it the factor reversal test. Averages of price variations can be converted into averages of quantity variations by interchanging the p 's and q 's. Consequently when the same formula with p 's and q 's interchanged is used on the same data, the results multiplied together should indicate the variation of the total values, which is a known magnitude.

Westergaard's test, which has already been mentioned, requires that the same result be obtained for a period distant from the base whether the price variations used are related to the base directly or indirectly through a number of intervening periods. When this test is applied to three periods, going from a first to a different second and then to a third exactly like the first, which is the same as going back from the second to the first, Fisher calls it the time reversal test (VII). The method of calculating the average variation from the first to the second and from the second

backward to the first should make the indices reciprocals of each other, so that on being multiplied together they yield unity, indicating no change. Further, if instead of one there are two or more periods intervening between the first and a later period exactly like it, it is equally evident that there is no change between the first and the last compared with each other, and therefore a measurement conducted through the intervening periods should likewise indicate no change when it comes to the end; that is, the intervening results on being multiplied together should yield unity. This is the circular test, or criterion VIII. Fisher rejects it on the ground that the weights of the intervening periods have no business in the comparison of the first and last periods and yet, not being similar as they are when the first and last periods are contiguous, they are not eliminated and therefore derange the result. This is true algebraically; but the fact remains that, since the last period is exactly like the first, no change ought to be indicated. Fisher shows only that no correctly weighted algebraic formula can do what the perfect method ought to do, but this does not logically invalidate the circular test. It is very closely approximated by the best formulae, and Fisher would not recommend his best formula unless it approximately conformed to the circular test.

There is no perfect formula satisfying all the tests. These are of different strength. Test V is inexorable. The first three are always fulfilled if the formulae are true averages. Tests IV, VII and VI are important, but they may be unfulfilled and the formulae still be good for ordinary price variations. Test VIII stands apart; when V, IV and VII, with or without VI, are fulfilled, VIII may be used to estimate the closeness of their approach to exactness—hence its supreme importance. Because Fisher did not use test VIII in appraising the relative accuracy of formulae, his appraisals are not trustworthy on fine points.

The fact that the best formulae which fulfil test IV fail to satisfy completely test VIII is responsible for the difference between two ways of conducting a series of measurements: by comparing every subsequent period with a base period; and by going from the base to the next, from this as a new base to the next and so on. The first, or the fixed base system, was the early practise and is still prevalent; the second, or the chain system, was first employed by Lehr. The two ought to agree, but they do not exactly. The first is better for comparing later periods all with the base, the second for comparing the later

periods with those near to them. Yet because of the high accuracy of some of the formulae, the difference between the two systems is inconsiderable if the former does not run too long on the same base. When both systems are employed they may serve to check each other.

Since the arithmetic average is the highest, the harmonic the lowest and the geometric lies between, the arithmetic mean, or average, will give results too high and the harmonic too low. This is confirmed by test VII, as was shown by Walsh. Fisher expressed this by saying that the arithmetic average has an upward bias, the harmonic a downward bias and the geometric no bias at all. He has also proved that the weighting of the base period has a downward bias and the weighting of the later period an upward bias. When two biases in the same direction are used together they intensify the error, but when opposite biases are used together they tend to neutralize each other, although not completely. The combination may be made by drawing a mean either between the weights of the two periods compared or between the results of a formula applied first with the weights of the one and then with the weights of the other period; these operations Fisher calls crossing. For this purpose the geometric mean is theoretically the best, but from the practical standpoint the arithmetic is almost as good and simpler; the harmonic, on the other hand, is neither practical nor simple and has therefore never been used. The geometric average of price variations with the weighting of either period alone becomes biased; but used with both it is unbiased and its error is diminished to an extremely small degree.

For a more detailed analysis Fisher's notation is employed. Let p' , p'' , p''' , ... represent the prices of different commodities; q' , q'' , q''' , ... the quantities of the same respectively; and v' , v'' , v''' , ... their values. Let subscripts 0 and 1 indicate the base period and the later period respectively. Then Jevons' imperfect formula with even weighting is

$$(1) \sqrt[n]{\frac{p_1'}{p_0'} \cdot \frac{p_1''}{p_0''} \dots \text{to } n \text{ terms}} = \sqrt[n]{\Pi \frac{p_1}{p_0}}.$$

Improved by double weighting with weights crossed it becomes

$$(2) \sqrt[n]{\Pi \left(\frac{p_1}{p_0} \right)^{\frac{v_0 + v_1}{2}}}, \text{ or } (3) \sqrt[n]{\Pi \left(\frac{p_1}{p_0} \right)^{\frac{v_0 q_1}{v_0 q_1}}},$$

where n , as always in similar positions, is the sum of the weights. Applied to only two commodities equally important and with quantities

constant over both periods, so that $\sqrt{q'p_0' \cdot q'p_1'} = \sqrt{q''p_0'' \cdot q''p_1''}$, formula (3) becomes (1) and $\sqrt{(p_1'/p_0') (p_1''/p_0'')} = (q'p_1' + q''p_1'') / (q'p_0' + q''p_0'')$, as can easily be shown algebraically. This is formula (11) below applied to the case of two commodities under the specified conditions, a case for which it is known to be absolutely correct. But neither (3) nor (2) is absolutely correct in general, although they may be very accurate for price variations and quantity variations such as ordinarily occur. Crosses of the weighted formulae are also possible:

$$(4) \frac{1}{2} \left(\sqrt[n]{\Pi \left(\frac{p_1}{p_0} \right)^{v_0}} + \sqrt[n]{\Pi \left(\frac{p_1}{p_0} \right)^{v_1}} \right),$$

$$(5) \sqrt[n]{\sqrt[n]{\Pi \left(\frac{p_1}{p_0} \right)^{v_0}} \sqrt[n]{\Pi \left(\frac{p_1}{p_0} \right)^{v_1}}}.$$

Formulae (2) to (5) apparently originated with Walsh in 1901.

Another attempt at the solution of Jevons' difficulty has been made by using an economic unit common to both periods. Drobisch initiated this method but made the mistake of using a common physical unit for all his commodities. His method worked out in a formula would give (6) $(\Sigma v_1 / \Sigma v_0) \cdot (\Sigma q_0 / \Sigma q_1)$, which is wrong because it violates test v. Lehr (*Beiträge zur Statistik der Preise* ... , Frankfurt 1885) corrected it but called the unit a pleasure unit on the mistaken opinion that units of equal exchange value are units of equal use value. In calculating it he used double weighting, which seems out of place. His formula is

$$(7) \frac{\Sigma v_1}{\Sigma v_0} \cdot \frac{\Sigma q_0 \frac{q_0 p_0 + q_1 p_1}{q_0 + q_1}}{\Sigma q_1 \frac{q_0 p_0 + q_1 p_1}{q_0 + q_1}}.$$

With geometric averaging it would be

$$(8) \frac{\Sigma v_1}{\Sigma v_0} \cdot \frac{\Sigma q_0 \sqrt[n]{(p_0 q_0 p_1 q_1) \sqrt[n]{v_0 q_1}}}{\Sigma q_1 \sqrt[n]{(p_0 q_0 p_1 q_1) \sqrt[n]{v_0 q_1}}}.$$

J. S. Nicholson (*A Treatise on Money*, Edinburgh 1888, p. 298-331) invented a somewhat similar but complex method, and it is difficult to make out what his formula should be. Walsh suggested the arithmetic mean and advocated the geometric mean as follows:

$$(9) \frac{\Sigma v_1}{\Sigma v_0} \cdot \frac{\Sigma q_0 (p_0 + p_1)}{\Sigma q_1 (p_0 + p_1)}, \quad (10) \frac{\Sigma v_1}{\Sigma v_0} \cdot \frac{\Sigma q_0 \sqrt{p_0 p_1}}{\Sigma q_1 \sqrt{p_0 p_1}}.$$

These two formulae are among the best, although not perfect as tested by VIII.

The earliest formulae were in fact although not always explicitly founded upon the following consideration: if the quantities of all the commodities are assumed to be the same at both periods, then

$$(11) \quad \frac{(q'p_1' + q''p_1'' + \dots)/n}{(q'p_0' + q''p_0'' + \dots)/n} = \frac{\Sigma q p_1}{\Sigma q p_0}$$

is absolutely correct. Of course this formula cannot be correctly applied in practise, since things do not so behave—not even family budgets, although these are generally assumed to do so. But if the quantities vary only slightly over the periods compared, it is approximately correct. This is Lowe's method with the q 's more or less carefully estimated. It has the appearance of being a ratio of the arithmetic averages of prices, and with the common n dropped it seems to indicate variation of price level. So viewed this method was long regarded as distinct from that of averaging price variations; and the relative merits of the two kinds were uselessly disputed. Yet Cauchy had shown it to be a weighted average of $p_1'/p_0', p_1''/p_0'', p_1'''/p_0''' \dots$ without fully explaining its nature. Fechner called it *das summarische Mittel*, which Fisher has translated into the aggregative average, or simply the aggregative. Algebraically it has two transformations:

$$(11A) \quad \frac{q'p_0' \frac{p_1'}{p_0'} + q''p_0'' \frac{p_1''}{p_0''} + \dots}{q'p_0' + q''p_0'' + \dots} = \frac{\Sigma q p_0 \frac{p_1}{p_0}}{\Sigma q p_0};$$

$$(11H) \quad \frac{q'p_1' + q''p_1'' + \dots}{q'p_1' \frac{p_0'}{p_1'} + q''p_1'' \frac{p_0''}{p_1''} + \dots} = \frac{\Sigma q p_1}{\Sigma q p_1 \frac{p_0}{p_1}}.$$

The first is the arithmetic average (A) of price variations with weights qp_0 ; the second the harmonic (H) with weights qp_1 . Thus the aggregative and these two are identical. All further methods that have ever been proposed are merely changes wrought upon this scheme by the assignment of special meanings to the q 's. Although closely akin Arthur Young's method may be regarded as a possible exception; its formula is $100 \Sigma v(p_1/p_0)/\Sigma v$ (12), where the numerical coefficient may be dropped. It is A with weights v , the factors of which— p and q —are undefined; and it differs merely by calling for an estimate of values while Lowe's requires an estimate of quantities.

If the q 's represent one physical unit of each commodity, i.e. if q equals unity, then formula

(11) becomes $\Sigma p_1/\Sigma p_0$ (13), which is Dutot's method; in transformation it appears as A with weights p_0 and as H with weights p_1 , which is absurd. If $v_0' = v_0'' = v_0''' = \dots = 1$ or 100, then formula (11) becomes the simple A and represents Carli's or Evelyn's evenly weighted method (14), essentially the same as is still used by the *Economist* and many others. In this method when later periods computed on a fixed base system are compared with each other, as e.g. the ninth with the eighth, the weights are p_8/p_0 for A and p_0/p_0 for H; this is uneven haphazard weighting, as was shown by Walsh in 1901. If $v_1' = v_1'' = v_1''' = \dots = 1$ or 100, then formula (11) becomes the simple H, Messedaglia's method (15).

If in formula (11) the q 's in the numerator are made to represent quantities of the later period and the q 's in the denominator quantities in the base period, then it is changed into (16) $\Sigma v_1/\Sigma v_0$, actually recommended by Edgeworth for affording "to the consumer a value in use varying with the national affluence." It is a measure not of the exchange value of money but of its esteem value—something quite distinct; it cannot be transformed into an average of price variations, for the weights must obviously be the same on both sides of the aggregative fraction. If the q 's be those of the base then (11) becomes $\Sigma v_0(p_1/p_0)/\Sigma v_0$ (17A), A with weights v_0 ; or $\Sigma q_0 p_1/\Sigma q_0 p_0(p_1/p_0)$ (17H), H with hybrid weights $q_0 p_1$. Either of these is the formulation of Laspeyres' method. If the q 's be those of the later period, then it is $\Sigma q_1 p_0(p_1/p_0)/\Sigma q_1 p_0$ (18A), A with the hybrid weights $q_1 p_0$; or $\Sigma v_1/\Sigma v_1(p_0/p_1)$ (18H), H with weights v_1 . Either of these is the formulation of Paasche's method. The Laspeyres and Paasche formulae, having neutralizing biases, are fairly good but erratic on opposite sides; they were declared by Haberler to represent the upper and lower limits to the general variation of prices. They can be improved by crossing arithmetically as follows:

$$(19) \quad \frac{\Sigma(q_0 + q_1)p_1}{\Sigma(q_0 + q_1)p_0}, \quad (20) \quad \frac{1}{2} \left(\frac{\Sigma q_0 p_1}{\Sigma q_0 p_0} + \frac{\Sigma q_1 p_1}{\Sigma q_1 p_0} \right),$$

or geometrically as follows:

$$(21) \quad \frac{\Sigma p_1 \sqrt{q_0 q_1}}{\Sigma p_0 \sqrt{q_0 q_1}}, \quad (22) \quad \sqrt{\frac{\Sigma q_0 p_1}{\Sigma q_0 p_0} \frac{\Sigma q_1 p_1}{\Sigma q_1 p_0}}.$$

Formula (19) was proposed by Marshall (in *Contemporary Review*, vol. li, 1887, p. 355-75) and Edgeworth independently and was recommended by the British Association committee, but so feebly as to pass unheeded. Formula (20) was

suggested by Drobisch in 1871 and Sidgwick in 1883 (*The Principles of Political Economy*, London, bk. i, ch. ii). Walsh recommended (21) in 1901, while (22) was sponsored by a number of investigators: by Bowley for measuring *aisance relative* (*Palgrave's Dictionary of Political Economy*, vol. iii, London 1899, p. 641), by Pigou for comparing price levels of different countries (*Wealth and Welfare*, London 1912, ch. iii), by Walsh as perhaps the best in axiometry (1921), by Allyn A. Young as the best measure of "the general level of prices" and by Fisher as the so-called "ideal index number."

To sum up the results of the argument thus far: the problem of obtaining a perfect formula has been approached along three different lines and certain close approximations have been obtained. First, there is formula (3) with (2) as a close competitor, perhaps even better; secondly (10), with (9) as alternative; thirdly (22), with (21) as rival and with (19) and (20) as practical substitutes.

Apart from the problem of formulae there are a number of questions regarding the data on which index numbers are to be based. To measure the exchange value of money for the country as a whole it would be necessary to have a complete knowledge of all the commodities and their prices and quantities. This is impossible: there are too many commodities. Only a limited number are employed; the most important are chosen and their wholesale prices used as being the most sensitive. Those included serve as samples. Mathematicians have elaborated a calculus of sampling at random, which does not apply here, because here the samples are not taken at random but on the contrary are carefully selected. Yet there is one principle of all sampling which Edgeworth imported into this subject: the erroneousness of any method is inversely proportional to the square roots of the numbers of units involved—not of the commodities named, for these are various multiples. Thus if an index number is based on forty commodities, and these the most important, the others to be added will be less important; and so, to halve the original inaccuracy, it will be necessary to increase the commodities not merely to 160 but to a considerably larger number.

Another source of error is the inaccuracy of the statistical data relating to prices and quantities. Here Edgeworth proved, first, "erroneousness of the results is less than that of the data," for errors of the data tend more or less to compensate and cancel one another; secondly, "in-

accuracy of the price-returns affects the result more than inaccuracy of the weights." Therefore, Edgeworth urged, "take more care about the prices than the weights." This was often misinterpreted as implying that it was not worth while to take any care about the weights and therefore, fallaciously, that it was sufficient to use an evenly weighted average, as if this were without weights.

The general exchange value of money, even of gold money, varies differently in different parts of the world; so also does that of the money of different classes of people in a country, even of the money of different individuals. When the money of classes, or as it is called, the cost of living, is being measured, then retail prices are used; in the case of the rich wages of domestic servants also should be included. There is no reason why there should be used here a different method of averaging and weighting from that which is preferable in measuring the money of the whole people.

INDIAN PROBLEM, NORTH AMERICAN.

See NATIVE POLICY.

INDIAN QUESTION. An oriental people, subject through a century and a half to western rule, moved at first by motives of racial self-respect and then by the poverty of its crowded masses, seeks to realize itself as a nation and to achieve self-government. Its traditional institutions and the divisions dating from earlier conquests hamper it in the struggle. That is the Indian problem as the present generation knows it.

The racial composition of this vast subcontinent shows much diversity, but it may suffice to distinguish four chief elements: the aboriginals, the Dravidians, the Aryans and the Mohammedan invaders. The first are jungle tribes of the Austronesian family, some of which have hardly yet begun to practise agriculture. This aboriginal element remains in pitiable degradation at the base of the social pyramid: to it belong the forty or fifty million "untouchables." The second element traces back to a civilization which began more than 5000 years ago in cities whose sites in the Indus valley have only recently been explored. It was akin to that of Sumeria and in contact with it; it possessed a script from which descend the alphabets of today; it had evolved an urban life of notable refinement and religious ideas which still retain their vitality. These proto-Indians survive as the Dravidian speaking peoples of the south but are an element in the population of the north. This bronze age civilization had been established for over a millennium before the coming (about 2500 B.C.) of the Aryans, who must have gaped at the marvels of the cities which their swords overthrew. Recent researches suggest that, while the Aryans imposed their language over the northern and central regions, the social structure and the popular faiths of Hindu India are a legacy from the pre-Aryan culture and its priestly class, the Brahmins. From this earliest civilization came the contempt for this trivial world of appearance; the discipline of yoga, which aims at power through austerities; the belief in the transmigration of souls; the doctrine of ahimsa (non-violence) and the system of caste—the characteristic beliefs and structure of Hindu society.

These beliefs and institutions created a rigid and static society, which could maintain itself indefinitely until outside forces broke upon it. To these it could oppose only the resistance of inertia. Caste is more than a stratification of society based on hereditary occupations: it specializes morality with function. Courage and the virtues of action belong to the soldierly castes; they have no place in any general civic ideal.

True citizenship was impossible under a caste system which all but deified the priestly class, condemned great multitudes (the Sudras) to a life of contempt and banished the untouchables beyond the social pale. A society so specialized, when it went on to forbid the taking of life either animal or human, weakened itself still further whether for aggression or defense. Something indeed of the old Aryan chivalry survived at the courts of princes and among the martial races. But as a whole Hindu society was schooled to an incredible acquiescence in the unreality of things as they are, including things as an alien conqueror might order them. Religion was narrowly salvationist, for its concern was the welfare of the individual soul. Here indeed is a prescription for a weak society, tenacious but endowed with little capacity for corporate movement or progress. At its base was the village commune. Under fleeting conquerors India remained a collection of about 700,000 village communities. Hindu civilization does not readily organize: it seems content with its two units, the village and the caste; it has thrown up dynasties but rarely made a living state; it has been prolific in theologies, but there has never been a Hindu church.

Hindu civilization was at its best during the Buddhist period, which flourished for over a thousand years from about 520 B.C. Buddhism represented the reaction of the humanitarian pessimism of India against the culture which the Brahman priesthood systematized. It was a movement of liberation, for it rejected caste: its atheism deposed both the Vedic and the Dravidian gods. In this congenial shape Hindu civilization became a missionary faith, created a humane and universal culture and achieved under certain of its emperors, notably Asoka, its greatest triumphs of art and its happiest ordering of society. But with the restoration of Brahman ascendancy caste returned and India relapsed into isolation.

Upon this mediaeval India, split into many unstable kingdoms, broke the successive waves of Mohammedan conquest. The invasion of Alexander the Great had been but a brief incident, although it left lasting traces upon art. The period of Mohammedan conquest began in the north with the eleventh century and lasted, if the period of decay is to be included, for eight hundred years. Its hold on the south was slighter, for a powerful southern Hindu empire survived to the end of the sixteenth century. The earlier Mohammedan conquerors, who felt a fierce contempt for idolatry, must have shattered

Hindu culture in the north with iconoclastic fury. The northern Hindus became with few exceptions a subject people, who paid as infidels a special head tax and were at times exposed to persecution. As late as the end of the eighteenth century Tippu Sultan in Mysore destroyed temples and converted Hindus by force. Some emperors, however, were tolerant, notably Akbar, the greatest of the Moguls, who sought for an eclectic creed. Some married Hindu princesses and employed Hindus as ministers and generals. The Mohammedan ideal of the equality of all believers attracted from the depressed castes masses of Hindu converts, who escaped in this way from the curse of untouchability.

Save to some extent in the northwest the Moslems do not today differ in blood from the Hindu population. The gulf that divides them is made by the incompatibility of the two creeds, the institution of caste, the pride of conquest and the memory of oppression. The Hindu religion, with its prohibition of marriage outside the caste and its minute regulation of food, combined with the pride of the conquerors to limit social intercourse. There were and are obstacles apart from intolerance which explain the slight influence that the two cultures have had upon each other. Language is not in India so grave a barrier to unity as is often supposed. The south indeed speaking Dravidian languages is thereby cut off from the north. But the chief languages of the north belong to the Sanskrit family and are so closely allied that Hindi (the language of Delhi) readily serves as a *lingua franca*. Unfortunately the Mohammedans in adopting it (under the name of Urdu) as their literary language mixed it with Persian and Arabic words and employed the Persian script. The literature of each creed is therefore inaccessible to the average reader of the other. The Mogul Empire had at its height a centralized administration of a feudal and military type, but it did not include southern India until the reign of the emperor Aurangzeb and it began to break up after his death in 1707. One cannot say that Indians were ever in the full modern sense of the word a nation. Yet over immense stretches of time they had a persistent common culture, and even under alien rule the habit of making pilgrimages to sacred rivers and temples mingled in emotional unity vast multitudes from every region of the peninsula and kept alive a love of the physical motherland. The Dravidian south, so strong is the cement of this Hindu culture, shows no separatist tendencies. It is the Moslem conquest alone which has made

a chasm across which it is difficult to realize national unity.

The Mohammedan rulers of India made it a member of the international world of Islam and brought to its shores a cosmopolitan culture. It remained, however, isolated from Europe until Vasco da Gama in 1498 opened the sea road. The motive of the Portuguese in their early settlements was trade, and they enjoyed a virtual monopoly of it throughout the sixteenth century. There was a prevalent belief in the fabulous wealth of India—a belief which has survived many generations of intercourse and which it is not easy to test. Then as now the princes possessed great hoards; and custom favored lavish display. India had thriving handicraft industries, and the pressure of the population on the land was not what it is today. Yet in the eighteenth century before foreign rule had brought about any organic change in economic life there is evidence of dire poverty among the masses. The "wealth of the Indies" was therefore probably superficial; yet the fact remains that by fair means or foul European adventurers could and did make fortunes rapidly in India.

The early European settlements had only the slightest influence on Indian politics and life. The extent of the territory occupied was trifling and did not range more than a few miles beyond the walls of the fortified ports or "factories" dotted round the coasts. Alone among the early adventurers the Portuguese professed imperial aims. The Holy Office figured among their imports, and they made converts under high missionary pressure. In the first years of the seventeenth century three competing powers, the British, the Dutch and the French, reached India almost simultaneously, broke the Portuguese monopoly by actions at sea and strove in turn for preeminence. The Dutch after half a century of effort on the continent were headed off to the East Indian islands. British progress was slow but continuous. The East India Company founded in 1600 had by 1619 four factories with Surat as its chief center; later in the century Madras and Bombay were also acquired. The aim of the company was the single minded pursuit of trade, and nothing in its deliberate actions presaged an imperial purpose until it became involved in Indian politics through the accident of the Franco-British wars of the eighteenth century. The pioneer of European empire in India was Dupleix, governor general of the French factories from 1741. Involved in the world wide struggle between England and France, with only

a handful of French troops to back him, he conceived the brilliant political design of intervening in the dynastic rivalries of the Indian princes and using his partisans to eject the British. The moment was a propitious one: the Mogul Empire was in rapid dissolution; Persians and Afghans invaded the north with impunity; the Mogul feudatories threw off its yoke; and adventurers found that with a troop of cavalry, a train of guns and a buried treasure dug from an ancient fort they could win a throne anywhere. Many were Mohammedans, but two military powers of Hindu origin, the Mahrattas and the Sikhs, were winning predominance in the central and northern regions. These undoubtedly reflected a crude nationalist impulse and a renaissance of Hindu patriotism based upon religion. This century must have been a period of deep misery for the masses, and Indian civilization amid the rapine and the cruelty was at its lowest ebb.

The struggles of the Europeans were while they lasted only an aggravation of the chaos. When battles were fought in which two hundred British troops under a clerk turned soldier, named Clive, aided by six hundred Sepoys and backed by the levies of a pretender to an Indian throne, faced a like number of French troops and Sepoys under Lally or Bussy backed by that pretender's cousin, it is improbable that the Indian people had any clearer perception of the fate that overhung them than had the merchant directors in London or Paris who regretted the interruption of trade. The first round of the struggle ended with the elimination of the French East India Company in 1769. The second was more interesting, for faint traces of the ideas of the French Revolution were reaching India. Tippu Sultan in Mysore planted a Tree of Liberty and called himself a citizen of the French Republic. French officers trained the Mahratta armies, and the loose Mahratta confederacy had a dim nationalist ambition and did for the generation from 1771 to 1803 attain command of Delhi, the traditional center of empire. Naval power decided the issue, however, and kept the French Revolution, save in hints and trickles, from India's coasts.

The events which decided the fate of India occurred in Bengal during the interval between the two Franco-British struggles with Clive as protagonist. It is impossible to tell here the ugly story of the conquest, stained by mutual ill faith, cruelty on the Indian and boundless rapacity on the British side. Bengal was won against a Mohammedan satrap, who cannot have focused the

patriotism of the people, at the battle of Plassey by a force of about 650 British infantrymen with 150 gunners and 2100 sepoyas. The Mogul emperor was induced in 1765 to confer upon the East India Company the administration of this province. In its early phase the company's rule was frankly predatory. Its generals (Clive among them) filled their own pockets as well as the coffers of the company by levying crushing tributes and indemnities. Warren Hastings paid for his wars of conquest by extorting ruinous contributions from princes who had accepted British protection. Officials grew rich by open bribery and private trade, until Cornwallis bought honesty by paying the high salaries which have been ever since the basis of discipline in the Indian civil service.

The evolution of the East India Company from a trading corporation into an administrative service proceeded rapidly in the last generation of the eighteenth century. Warren Hastings created law courts for Bengal and drafted a legal code in 1772, and a Regulating Act (1773) surrounded the governor general with a council. But it was in Pitt's India Act of 1784 that the English ruling class clearly revealed its intention to assume responsibility for the government of India. Controversy raged around the conduct of the early proconsuls; Warren Hastings had to stand his trial, and Burke's sympathies (as later during the French Revolution) were readily enlisted on behalf of injured princesses. Should one ascribe it to the awakening of conscience or to class interest that this bill took from the city merchants who directed the company the right to appoint the governor general and conferred that right on a minister? This post, which soon ranked among the great prizes of politics, usually fell to an aristocrat. The consequences of the new outlook were apparent when Cornwallis, the first of these political viceroys, made the Permanent Land Settlement of Bengal in 1793. This created a class of landlords (before the days of the company these persons were merely tax farmers) and robbed the peasantry of its traditional ownership of the soil. It did indeed stabilize for all time the taxes which these magnates paid, but it has allowed them to raise their rents twelve or thirteenfold.

The history of the next generation is a record of incessant conquest. The decisive event was the subjection of the Mahrattas by Lord Wellesley in the years 1802 to 1804. Since they were the custodians of the decadent heirs of the Mogul throne the British succeeded to their vague su-

premacy. While Bengal and some smaller areas were administered directly, the greater part of India came under a quasi-feudal "subsidiary system," which exacted tribute from the native prince and required him to become the ally of the company, to accept its mediation in his relations with his neighbors and to refrain from employing hostile European officers. The restoration of a central power strong enough to impose internal peace throughout the peninsula ended a century of anarchy and was unquestionably a gain to India, for no tradition of humanity had restrained the warlike princes, the bandit armies (Pindaris) and the religious fanatics (Thugs). The directly administered areas (mainly Bengal) gained also from the establishment of courts which no longer sold their verdicts. The police, mostly Indians, were and still are both corrupt and brutal but at least they made life and property secure. In short, the first gift of British rule was the creation of an efficient police state, which maintained order and contributed to economic stability.

Two losses must be set against these gains. The village communities, which had kept their vitality under the Mohammedan conquerors, administering justice, assessing taxes and maintaining the school, the temple and the water tank, decayed under the individualistic emphasis of British rule. Still more serious was the deliberate destruction by prohibitive export duties of the fine textile industries of Bengal. While the European market was thus closed to the exquisite products of Indian hand looms, the Indian bazaars were opened wide to the cheap machine made cloth of Lancashire. First the weavers and then the potters and the smiths were compelled gradually to abandon their crafts; they could now live only by tilling the soil, and so began the pressure on the land which continues to this day. The average size of peasant holdings diminished with each generation, while rents were enhanced by the bitter competition, as the ever increasing millions struggled to gain a subsistence from overcrowded acres. By abolishing war, the first of the Malthusian checks, British rule did much to create the most tragic of India's problems, overpopulation. Famine and plague still remained as checks, but with these in turn the administration learned to cope. The population doubled itself under British rule, but no attempt was made until the present century, and then only on a small scale, to improve methods of cultivation, while the flood of imported machine made goods lessened the alternative ways of

getting a livelihood. Much of this was in a measure inevitable; if no armed Europeans had ever landed in India, the products of their machines would still have invaded it. But the process under a less efficient oriental administration would have been more gradual; and intelligent Indian rulers would have checked it and fostered native machine industry by tariffs. The British government, on the contrary, down to 1924 pursued a policy primarily of encouraging British imports, especially textiles from Lancashire: its program in India called generally for imposing free trade, and when a tariff for revenue was levied it was counterbalanced by an excise tax on the Indian products. India lay passive under the impact of the machine age; it had no government by which it might have reacted (as Japan did) to the new conditions and thus eased the process of adjustment.

One notes toward the end of the company's rule the gradual humanizing of its aims. In 1833 it ceased to be a trading corporation. Bentinck in 1829 broke with its traditional neutrality in matters of religion by forbidding the immolation of widows. Under Lord Dalhousie the company had a wide range of activities and gave evidence of a new concern for the good of its Indian subjects, which carried it far beyond the limits of the early police state. The most significant of these activities was the creation in 1854 of a system of education which included the establishment of universities. The policy, adopted on Macaulay's advice, was to base a mainly literary curriculum on the English language; and Macaulay predicted that in a generation India would turn Christian. In 1848 Dalhousie also created a public works department and a beginning was made with irrigation works, which conferred immense benefits on the peasantry. It is significant that he also started railway building and inaugurated the electric telegraph. His administration was marked by military expansion as well. Wars raged from the Punjab to Burma. The Sikhs were subjugated and one native throne after another was emptied. The case which attracted the most attention, the deposition of the king of Oudh, was a punishment for gross misgovernment; but his fall none the less moved his subjects to hot resentment.

At last, eighty years after Indians had ceased to govern Bengal, came the first popular outbreak against British rule. The Sepoy Mutiny of 1857 was much more than the revolt of discontented mercenaries; it was the first crude expression of Indian nationalism. It is significant that

for several years before these events, notably in 1853, petitions were reaching Parliament praying for the nomination of "respectable and intelligent natives" to the governor's councils. The history of the organized conspiracy is still obscure, but while it began as a mutiny in certain Bengal regiments it became an attempt to revive the Mahratta and Mogul dynasties. Its immediate occasion was the belief of the sepoys that cartridges greased with the fat of cows and pigs had been served out to them with the deliberate purpose of defiling them. What is significant is that a belated perception had reached the popular mind that India was being rapidly westernized. The extinction in rapid succession of several Indian dynasties seems to have been the chief fact that influenced popular feeling; but other evidences of the advent of an alien civilization—the railway, the telegraph and the schools—may have played their part, as similar experiences in China did in provoking the Boxer rising. The mutineers behaved with great barbarity, and the suppression of the mutiny under certain commanders was carried out with a ruthlessness that left bitter memories behind and crushed the spirit of the people for a generation, despite the determination of the viceroy, whom the English in India nicknamed "Clemency" Canning, to follow a policy of conciliation. On the English mind it left a sense of insecurity which lingers to this day. The possibility of a second outbreak is never forgotten. The reinforcement of the white garrison increased the cost of Indian defense; but the deepening of the gulf between the two races was a still more deadly consequence.

With the suppression of the mutiny a new era began. The East India Company was compensated (at the expense of India) and disappeared, and paramountcy over All-India together with the direct administration of British India passed to the crown. The main constitutional change was that the responsibility of Parliament was exercised through a secretary of state assisted by an advisory council consisting mainly of retired officials. The administration was now a powerful bureaucracy distinguished by a strong corporate tradition, which is sometimes able by the threat of resignation to maintain its own views against the check exercised by the secretary and cabinet in London. The Indian civil service recruited mainly from the professional classes by competitive examination has a reputation for a high level of ability and is as hard working as it is incorruptible. It shares, however, the general fault

of the English in India. It lives aloof from the social life of the people; it suffers from an exaggerated sense of racial and official prestige and tends to a certain arrogance of manner, although there are distinguished exceptions to these generalizations. Human nature is rarely equal to the strain of omnipotence, especially when the barrier of color intervenes between rulers and subjects. The English in India whether officials, soldiers or merchants lead their own social life in cantonments cut off from the native town and find their recreations in closed white circles which frown on any intimacy with Indians. English women rarely know much of the "natives," save that they must manage their numerous servants. The most painful aspect of this relationship is the contempt which the less sensitive members of the British community too often display toward Indians, although of late years somewhat self-conscious efforts have been made to promote social intercourse.

Indians feel a certain respect, mingled with fear, for the honesty and capacity of their English rulers; but with this there goes a bitter sense of humiliation, which has increased as education has fitted them to criticize. The tension is greater as the intellectual gap narrows. The Indian professional class, especially the lawyers, was the first to resent the stigma of racial inequality. The relations of the English with the less highly educated and therefore less critical elements of the population, the Punjabis, the Moslems and the "martial races," whose dignity and pugnacity exact a measure of respect, have always been better than with the average upper and middle class Hindu, who is by tradition singularly courteous, incredibly gentle, sedentary in his habits, with little of the normal male impulse of physical resistance to insult and wrong, although he compensates for its absence by dialectical skill. This combination of talents and deficiencies is nicely designed to irritate the average Englishman without extorting his respect.

The British conquest in spite of the highly trained English conscience and the gifts of physical science, mechanical efficiency, order and security which came with it was thus for India's self-respect a uniquely painful experience. Its earlier conquerors, Aryans, Greeks, Pathans and Moguls, settled in the country, intermarried, lost their white skins and became Indians. The British, who never settle or rear children in India, have today, thanks to the growing ease and cheapness of travel, less sense of their permanent personal stake in India than they had in

earlier generations. The consequence is an economic complication which earlier conquests did not raise—a steady “drain” of wealth from the subject dependency to the imperial metropolis. British officers and officials remit part of their pay to their children at home, draw it during frequent and lengthy furloughs and qualify at an early age for pensions which they enjoy in England. There are other “home charges”: for the expenses of the India Office in London, the purchase of stores and the service of the sterling public debt, much of it productive since it has gone into railway building and irrigation, some of it due to past wars. Of the drain in this narrow sense Indian opinion became acutely conscious in the latter years of the past century, when it amounted roughly to the whole sum drawn from the peasantry in land revenue. A partial justification was possible. The officials and soldiers sold services to India which Indians could not at this time render. The productive debt has developed India's resources, and this capital either could not have been raised in India or would have borne a higher rate of interest. Even the cost of the army and police could be justified on economic grounds: security is an indispensable condition for the wealth of nations. None the less the fact remains that year by year this considerable sum is deducted from India's income and ceases to evoke goods and services there, as even a tribute of a far cruder kind would have done if paid to conquerors settled in the country. In its wider sense this drain includes also the profits of European enterprise in India, banking, shipping and industry, in so far as these find their way to investors at home. Such profits often represent an unconscionable exploitation of Indian labor, which is cheap even when allowance is made for its inefficiency. In a good year the European jute mills of Calcutta will make \$500 for their shareholders in Scotland for every \$60 which they pay in wages to Indians. India now exports in a normal year a value of \$400,000,000 above what she imports, a balance which may be taken as a rough measure of the total drain.

If the legend of Indian wealth invited her conquerors, the salient fact today is the unimaginable poverty of the masses. One may say roughly that for every pound (taking it at \$5) which the average Englishman enjoys the average Indian possesses only a rupee (1s.6d or 37.5 cents). It would be grossly unjust to attribute this poverty mainly or directly to the British conquest, although taxation and the drain play their part. The explanation begins with the low

physical stamina of the laboring population, due to semistarvation, malaria and other preventable diseases, insanitary housing and early marriage. Women contribute less than they do in the West to this labor power of the nation, and children too much. In the villages the entire population is necessarily unemployed for about a third of the year. To these explanations of the low production of wealth one must add the general illiteracy. In agriculture the methods of cultivation have hardly improved since the bronze age. Forty days of one man's labor will be spent in the various processes required to raise an acre of wheat, where a fraction of one day would be required on a modern mechanized farm. Yet the Indian peasant must sell his wheat at the world price. Animal husbandry is handicapped by the Hindu tabu on the taking of life; the scanty fodder of the tropical summer is consumed by useless herds of aged and half starved cattle, and yet even in the villages the average Hindu child never tastes milk. Hindu religion forbids any measures for the destruction of animal pests, creates obstacles to the use of manure and interferes through caste restrictions with the economical organization of labor. Subject to these handicaps the soil produces for vegetable and animal husbandry a mere fraction of what it would yield under scientific organization to a vastly smaller force of efficient workers. Nor is this all. The wealth produced in inadequate quantity is ill distributed. Almost every peasant is in debt from the cradle to the grave; the village usurer will charge a rate ranging in most cases from 37½ percent upwards and always at compound interest. The landlords (zamindars) under the system which prevails throughout northern India are a parasitic class, who have laid out no capital on improvements, irrigation, drainage or cottages, perform no social function, attempt no scientific management of their estates and levy a tribute which they make no pretense of earning. Official figures show that the landlord's share of the produce of the fields may sometimes amount to as much as three times what the peasant enjoys.

One cannot acquit of some measure of responsibility a government which presides over poverty so terrible. The company, ruling as a mere incident to its trading operations, was indifferent. In the early days under the crown able and conscientious officials trained in the Victorian tradition at English universities believed firmly in *laissez faire* and had no conception of what a government might do to raise the level of

its subjects' economic life. Forced to spend disproportionate sums on the army and the service of the debt, to say nothing of their own salaries, they shrank from the additional taxation which any adequate system of popular education would have demanded. Even today schooling has been made compulsory only in a very few experimental districts. The advance to a more constructive conception of the functions of government became noticeable in the early years of this century under Lord Curzon. The first agricultural research station dates from 1904; cooperative agricultural banks were started the same year; shortly thereafter efforts were made to distribute improved seeds to the peasants. Something also was done to encourage small native industries and to improve the tools of the craftsmen. Medical work also showed steady progress, and factory legislation attempted to effect some improvement in the health of urban workers. All these efforts, however, came at a late date and then only on a scale so small that as yet they have made hardly a perceptible impression upon the hopeless mass of Indian inefficiency, ignorance and ill health. Only eighteen men and not two women in a hundred can read, while the death rate in the native cities is almost four times that of the European cantonments, where white men live under the same burning sky but enjoy sufficient food and adequate sanitation. Again, very belatedly, a break was made after the World War with the doctrines of the Manchester school, which had retarded the creation of native machine industry. Indian steel production was fostered by tariffs and by bounties, while Indian cotton mills enjoy protection to the extent of a 15 percent duty even against the imports of Lancashire. Had these new departures in social and economic policy been initiated half a century earlier, Indian poverty would have been less terrifying and Indian history might have had another course.

A generation elapsed after the mutiny before one again recognizes an Indian nation attempting to play an active part in Indian history. When it did again emerge it spoke the English language and thought in terms of the Victorian liberalism which it had learned at the feet of English masters. Macaulay's system of education was now bearing fruit. It made very few Christians, but it did teach Indian intellectuals to judge by its own western principles the bureaucracy which governed them. An Indian owned press, some of it in English and some in the vernacular, was growing in influence and with it an advance guard of

men trained in the universities and nourished on the doctrines of Burke, Macaulay and John Stuart Mill. Working at first in isolation, the leaders of provincial opinion came together in 1885 to form the Indian National Congress. Its founder was actually a retired English official, Hume; and at least one other, Sir William Wedderburn, was later its president. The Congress was for many years an extremely moderate organization, from time to time celebrating in its resolutions the blessings of British rule and advancing only very slowly toward the ideal of self-government. It was in its first phase a liberal rather than a nationalist movement. It used, as indeed it still does, the English language in its annual conferences; and its membership diffused over the whole peninsula was at that time confined to the educated middle class. Its quarrel was with autocracy and bureaucracy and not with the British connection. It pressed for the representation of Indian opinion in the advisory councils, for equality before the law, for the separation of the judicial and administrative branches of the service, for full liberty of the press and for the remission of burdensome taxation. It educated Indian opinion, brought its leaders into cooperative contact and began to focus the vague strivings for national unity. Although it was the fashion to deride it as the voice of a handful of intellectuals who did not represent the silent and supposedly contented millions, it had a considerable influence on the government. The act of 1892, which reformed and expanded the legislative councils, was passed in response to its agitation.

The Congress grew bolder in the new century. Leaders arose, notably B. G. Tilak, a masterful and eloquent Brahman with the Mahratta tradition in his blood, and Lajpat Rai, a Punjabi with socialist leanings, who had a mass following. These men were feared and repressed, but repression was in vain and each period of imprisonment only served to canonize the leader who underwent it. Chiefly under Tilak's influence the movement was becoming consciously nationalist. If this kindled the zeal of Hindus, it caused Moslems to hold aloof.

What is the content of Indian nationalism? In the negative sense it aimed at first at checking foreign rule, then at its subordination to Indian democratic control or in the last resort at its overthrow; above all it aimed at racial equality. On the economic side also there was little difficulty in union, for all creeds and races could join in the complaint of exploitation, in agitation

against the financial drain and in criticism of the advantages which British commerce enjoyed. This economic nationalism became increasingly vocal and found practical expression in an organized swadeshi movement for the preferential encouragement of Indian wares and industries, especially cloth. This led to a demand, ultimately successful, for the introduction of protective duties into the revenue tariff and it prepared the way for the later boycott of British goods.

But nationalism always craves an ideal content even in the West, and India felt this impulse even more consciously than others. For its attitude to the West in general and toward its British rulers in particular is one of reaction against their "materialism." This has at times taken a defiant form. Scholarly men have been known to lead an agitation against sanitary measures designed to cope with epidemics. One often encounters more than an indifference to physical science—an active hostility toward it. In these moods India will reject the microscopes of the British along with their machine guns. There has been in recent years a marked revival of the wholly empirical Hindu system of medicine. In these developments the advance guard has made a right about turn, when one compares its direction with that of the reform movement of the last century, which was liberal and rationalist. A happier phase of this intellectual nationalism was the revival of literature, music and dancing in Bengal under the leadership of Rabin-dranath Tagore. He aimed indeed at a marriage of East and West (with the vow of obedience omitted), but he insisted somewhat in the spirit of the Russian Slavophiles on the peculiar mission of India as the custodian of certain spiritual values and of a national outlook on life. What outlook is this? Can one separate it from that persistent Hindu culture, that mystical approach to reality, which scholars detect already in the art of the buried cities of the Indus valley? It reappears five thousand years later in Gandhi's sermons. This religious spirit, this specifically Hindu idealism in the Congress movement, must be deemed to account in some degree for the obstinate aloofness of the older generation of Moslems. A nation must have its own culture. But is there an Indian culture? Can a man who believes in Islam with its militant affirmations, its still more resonant negations, feel at home with Hindu mysticism? Hindus and Moslems seem to dispute over tangible things, but at bottom the force that divides them is that hammer

of the old iconoclasts who smashed the Hindu temples. Hindu nationalism is at grips with two conquests at once. It must absorb Pathans and Moguls before it can present a united front to the British.

This analysis of the growth of Indian nationalism has carried us ahead of the political events. The victories of Japan over Russia brought a new temper to the East, which at last dared to think that white men are not invincible. Lord Curzon's reign as viceroy, in many respects a time of social progress, saw the outbreak in Bengal of a revolutionary movement. The occasion was the partition of Bengal into two provinces in 1905. The old area was unmanageably large, but this autocratic act roused the spirit of Bengal's nationalism to hotter flames of anger than India had known since the mutiny. Terrorist assassinations and dacoities (brigandage with a political motive) stood out against a background of general if passive revolt. Lord Morley undid the partition and introduced the first unmistakable steps toward representative self-government in the years 1907 to 1909. The Morley-Minto reforms when viewed in retrospect inaugurated a policy of conceding Indian home rule by instalments, although John Morley himself stoutly asserted that England would never surrender to the people of India the responsibility for its government. While the elected now predominated over the official element in the councils of the provinces, although not in the central legislature, they were powerless, save for criticism. The result was to confirm Indians in their habitual attitude of embittered and irresponsible opposition. Morley made, however, a bold break with tradition when for the first time he appointed an Indian to a ministerial post on the viceroy's council, while others were chosen to serve on the less influential advisory council in London. Once and once only for a single year an Indian served as governor of a province. The appointment of Indians to important offices has continued since Morley introduced the practise, with less effect than one might have anticipated. The choice falls on cautious and moderate men, who are surrounded by experienced British officials and lack the support of an organized party.

The franchise laid down in the Morley-Minto reforms was extremely restricted, and the system of separate electorates for the Mohammedan and Sikh minorities was introduced, a system which ever since has been the curse of Indian politics. It was necessary to assure these minori-

ties that they would not be swamped by the Hindu majority. Both proportional representation and the simpler system of the reservation of seats (i.e. a provision that of the members elected a fixed proportion must belong to the minority community) were rejected. Mohammedan, Sikh and Hindu voters were and still are registered on separate rolls. Within these closed compartments they each elect their own members. There can be no rivalry, but equally there can be no co-operation. Every candidate must recommend himself as a stalwart defender of the faith; and since it suffices to talk religion in order to recommend oneself to the electors, parties can evade the necessity for clearly formulated social and economic aims. This false start gravely retarded the political development of India and helped to give to the old rivalry of the religious communities a new economic basis. Each became acutely conscious of its numerical proportion to the whole population, and the claim was now made by Moslems and accepted by the British that a balance should be observed in all public appointments. If a Hindu was promoted to the viceroy's council a Moslem must be found to sit beside him. This principle was soon extended to the humblest ranks of the public services. The consequences to efficiency may be guessed, but more serious still is the degradation of both politics and religion. Faith has become the qualification for jobs.

If Japan's victories over Russia in 1904-05 heightened India's national consciousness, the World War had a still more decisive effect. India showed a rare chivalry in refusing to take advantage of the empire's danger; it filled the empire armies by voluntary enlistment. Even the pacifist Gandhi went on a recruiting campaign, and contributions to the cost of the war were voted with enthusiasm. England for a time was genuinely touched by this spectacle, and promises of reward in the shape of self-government were lavishly made. The realization, however, was slow, and inadequate when it came. With the end of the war began a period of acute unrest. The Afghans invaded the northwest and were with difficulty repulsed in an indecisive campaign. The Mohammedans, usually the loyal and conservative element, had been alienated by the partition of the Turkish Empire, which involved the abolition of the caliphate. Inflamed by this grievance, they made common cause with the Hindus. The fraternization went so far that Moslems were invited to preach in temples and Hindus in mosques. The Indian people wit-

nessed the revival of Arab nationality; they heard the Allies proclaim at the expense of the vanquished powers the doctrine of self-determination, and inevitably they applied it to India. To cope with this unrest the government passed the repressive Rowlatt Act, which struck a heavy blow at all civil liberties and especially at the freedom of the press. At this point a new leadership came to the fore. The Congress had lost its moderate element by the secession in 1919 of the Liberals, a body of able and influential men, who have, however, no mass following. It now organized the agitation under Mahatma Gandhi, who first won his unique position as the champion of the oppressed Indian immigrants in South Africa.

Nature did little for this original personality. Insignificant in physique and with none of the gifts of an orator, he has nevertheless in his personal contacts a charm to which all submit, a disarming modesty and a sense of humor rare among Indians. He assumed the part of an ethical and religious teacher and prescribed a way of life which implied a return to the severest ascetic traditions of the Hindus. In his rejection of force, his preaching of absolute chastity and temperance, his indifference to science, his rejection of the entire mechanical civilization of the West and his adoption of the village as the natural unit of a loosely organized society he recalls Tolstoy in his later years. But unlike Tolstoy he conceived of non-violence (*ahimsa*) as an active method of resistance through the organized refusal of the people to acknowledge the government. Toward the British government his attitude from this time onward was one of absolute opposition. It was for him a "Satanic" government, which had emasculated India, destroyed its traditional social structure, sapped its self-respect and impoverished the "half-starved millions" of its villages. It became a mere question of expediency whether India, like Ireland, should content itself with dominion status or insist on unfettered independence. This was a new note of radicalism; almost equally novel was the emphasis on the misery of the poorer peasants. Here was a new type of leader with a new conception of tactics. His predecessors had been men who thought in western terms even while they were creating Indian nationalism. When Gandhi spoke, India for the first time heard itself thinking aloud. His dominating idea (*ahimsa*) had been hers for thousands of years; his method of silent protest (the *hartal*, which means rather a public mourning than a general

strike) had always been the traditional expedient of the East for checking tyranny. India had always believed that a saint could by his austerities control the universe; this rooted faith in the power of self-discipline Gandhi turned to political account.

This ascetic, whom Indians have trusted and revered because of the purity of his life, is at the same time a shrewd tactician and an organizer. Gandhi will rank in history as a remarkable teacher of morals, but his thinking presents to the western mind a baffling series of impulsive and disjointed exaggerations. His agitation is directed especially against the excessive cost of the British army and the civil service, the salt tax and the liquor monopoly. The salt tax is doubtless a bad tax, but there are a dozen causes of peasant poverty better worth fighting than this. Many of them lie, however, rather in the structure of Hindu society and in its religious tradition than in the sins of omission and commission of India's foreign rulers on which nationalism incessantly broods. Again, while Gandhi's prescription of a revival of hand spinning as a cure all for village poverty is less unreasonable than his western critics commonly suppose, it is pitifully inadequate when it is offered as the main item of an economic program. As a constructive thinker he is obsessed by the belief that Hindu village society as it existed before the irruption of western industrialism was ideally happy. Starting with these preconceptions he has never faced the immense problems of reconstruction with which India must grapple if the standards of her population are ever to approach those of the West. These oddities in his constructive thinking are evident enough to westernized intellectuals. But such is his genius for revolutionary action and such the faith of the masses in his leadership that criticism from within the Hindu camp is silenced.

Gandhi's first essay in leadership was the proclamation of a nation wide *hartal* as a protest against the Rowlatt Acts. It was an impressive demonstration, but occasional acts of violence occurred, notably at Delhi, and the police were prompted to shoot. There were fears of a general rising in the Punjab. The officials were nervous, as well they might be with an Afghan invasion under way, for even the Moslems were disaffected. Clumsy handling of crowds at Amritsar in the Punjab turned them into a maddened mob which murdered two English bank managers and seriously injured a lady missionary. The officials reacted to these outrages with a fury which has

left its indelible mark on Indian history. Every Indian who passed through the street where the missionary had been beaten was compelled to crawl on his stomach. In cold blood after the riots were over on April 13, 1919, General Dyer, finding a prohibited but peaceful meeting taking place in an enclosed garden, mowed down the unresisting demonstrators with machine guns, left 379 dead behind him and marched off without rendering first aid to about 1200 wounded. The gravest excesses occurred under martial law throughout the Punjab. As so often in India, false notions of prestige and of loyalty to subordinates stood in the way of redress. General Dyer was indeed relieved of his Indian command, but the House of Lords by a formal vote registered its disapproval even of this mild censure and a sum of \$100,000 raised by public subscription was presented to the man of Amritsar.

The failure to punish this massacre, even more than the thing itself, drove the Congress into open if non-violent rebellion. In August, 1920, Gandhi, who had been named dictator, making full use also of the Moslem anger over the fate of Turkey, called for all round "non-cooperation." British goods were boycotted; students quitted the government's schools and lawyers ceased to plead in its courts. But the masses did not understand non-violence. In the summer of 1921 the Moplahs, fanatical Moslem tribesmen of Malabar, rose in armed revolt and fell upon Hindus as well as Englishmen. There was rioting in the autumn when the prince of Wales visited Bombay. In vain did Gandhi punish his own frail body by fasting; a still worse outrage occurred at Chauri Chaura in February, 1922, when twenty-one policemen were burned to death in their barracks. Gandhi confessing that he had made a "Himalayan miscalculation" put an end indefinitely to the attempt to win freedom by non-cooperation. Amid the dejection and derision which followed this characteristically unworldly retreat the government, which had hesitated to deal with a saint turned rebel, now struck. In March, 1922, Gandhi was sentenced to prison for six years, but a dangerous illness led to his early release.

The national struggle was now transferred to the legislative councils. The new measure of reform promised in 1917 was avowedly a half way house on the road to self-government. That goal, however distant it might be, was set and the plan of a periodical revision adopted. This gradualism may have been inevitable, but it meant a continuance of the unrest, since the scope of the

next concessions might depend on keeping up the pressure of agitation. The Montagu-Chelmsford reforms enacted in the last days of 1919 (for the Montagu-Chelmsford report see Great Britain, Indian Constitutional Reforms, *Report*, Cmd. 9109, 1918) involved a cautious yet appreciable surrender of power to the elected councils both central and provincial. A nominated minority composed largely of officials sat in them to dilute democracy, and the franchise was restricted. The viceroy and the governors had an unlimited power of veto and might carry legislation, including the budget, by "certification." But in the provinces certain departments, which included education, agriculture, commerce, labor and local government, were entrusted to Indian ministers who were responsible to the councils. The concession was, however, largely illusory, since finance remained a "reserved subject" in official keeping. The bureaucracy retained its grip also on the machinery of law and order. Gandhi declared for a boycott of the elections to the councils, a sterile policy; and eventually Das, the Bengali leader, carried the main body of Congress with him in his advocacy of a policy of constitutional opposition within the councils. The Congress had a majority in some of the councils, but it refused to enter the ministries and by obstruction was sometimes able to render the conduct of business impossible. The government was driven to compose unstable majorities by trading jobs and honors in return for votes. The responsible ministers, who rarely had behind them an organized party based on a social program, showed little independence or ability, and behind these transient figures the bureaucracy still governed. Bengal had the worst, the Punjab and Madras the best experience with this system of "diarchy," which had in the end no defenders even among officials. During this period tension between Moslems and Hindus became once more habitual and was indeed increased by the scramble for posts.

The nationalist movement was at its lowest ebb in 1926, when Lord Birkenhead revived it by an act of clumsy arrogance. By way of preparing for the next instalment of reform he appointed a commission under Sir John Simon, drawn from all parties but consisting exclusively of Englishmen, to visit India and report on its fitness for a further advance to self-government. They were met wherever they traveled by *hartals* and only the tamer Indian politicians consented to give evidence before them. The report of the Simon Commission (Great Britain, Indian

Statutory Commission, *Report*, 17 vols., London 1930; vols. i-iii Cmd. nos. 3568-69, 3572), able though it was as an analysis of a complicated problem, was received in India, when eventually it was published, with a unanimous howl of anger, in which even the more conservative Moslems joined. It proposed no advance at the center but did advise responsible self-government in the provinces.

This episode raised the emotional temperature to revolutionary heat. The Congress which met at the end of 1928 gave the British government one year in which to grant dominion status to India, failing which the Congress would declare India's absolute independence. The coming of the Labour party to office in May, 1929, made a new departure possible and this was attempted by Lord Irwin, one of the few British viceroys whose personality has won the trust and affection of Indians. In a binding official pronouncement in October it was explicitly affirmed that the attainment of dominion status was the goal of British policy in India. The insult of the one-sided Simon inquiry was wiped out by the offer of a Round Table Conference at which Indian and British statesmen would together work out the future constitution. For a moment these concessions seemed to have won Indian opinion, but when Gandhi in quest of further precision failed to obtain a pledge that the MacDonald government would propose to the Round Table Conference a dominion constitution, albeit with transitory safeguards, the Congress decided to carry out its uncompromising program. In January, 1930, it declared India's independence, hoisted a tricolor flag and renewed the struggle of 1921 by non-violent non-cooperation. It is probable that if in 1929 MacDonald had promised what he actually conceded in January, 1931, at the end of the first Round Table Conference, he could have had peace in India, but it would have been at the price of a struggle at home and a probable defeat. Neither the Liberal nor the Conservative party was then prepared to yield self-government at the center. They were persuaded of the necessity for that concession only by the demonstration of India's massive determination to win it.

The success of "civil disobedience" came as a surprise. There was on the Indian side an amazing restraint, and the few instances of violence which did occur seem negligible when one considers the vast extent of the movement. It was weak throughout the south and in the Punjab, but it had the support of the vast mass of

the Hindu population throughout the north and the center. The younger, educated generation of Moslems on the whole sympathized with it and even joined it; the older generation did nothing to frustrate it. At its height in the Bombay presidency it seemed to embrace virtually the whole Indian population. It surpassed in two respects every previous effort. The Hindu women came out of their seclusion, walked in its processions, risked physical injury at its demonstrations, formed the main body of the picketing forces which carried out the boycott of British goods and went in thousands to prison. In the second place the agitation won the peasants even of the remoter villages. There were many villages in which every male peasant wore the white Gandhi cap. The explanation lay partly in the growth of racial and national consciousness and partly in Gandhi's mesmeric hold upon the masses. But the principal new factor was economic. The world depression fell on India with the force of a tropical typhoon. The prices of agricultural produce fell by a half between the harvests of 1929 and 1930. This alone would have meant ruin to the peasants; but their case was further aggravated through the depreciation of silver, which robbed them of the poor savings hoarded in their women's ornaments, and through the raising of the exchange value of the rupee, which added 11 percent to India's external debt. Amid this economic misery the nationalist agitator had an easy task.

The methods of civil disobedience which the Congress adopted rose in a calculated crescendo. First contraband salt was manufactured from sea water. Next the liquor shops were picketed, a serious attack on the budget of the provinces, which draw a fourth of their revenue from the liquor monopoly. The boycott of foreign but especially of British cloth struck at once at Lancashire, at the British merchant community in India and at the customs revenue. In the villages administration was disorganized by the resignation of headmen. In some districts the villagers refused to pay the police rate. The final challenge, the refusal to pay land revenue, was attempted at first only in Gujarat. The peasant, who in this region owns his land, risked the confiscation both of his holding and of his stock. This whole villages and districts faced, acting with an astonishing solidarity which the highly organized castes enforced with fines backed by the social and spiritual penalty of outcasting. Many thousands even deserted their villages and camped in brushwood shelters on the territory of

the neighboring state of Baroda. Gujarat is one of the most prosperous regions of India, and its peasant owners have the stubborn spirit of yeomen. More complicated and significant was the case of the United Provinces, where the peasants are tenants who could not withhold the land tax without also refusing to pay rent. The Congress was reluctant to call upon them to take this extreme action, which would antagonize the landlords, who are often its supporters. The peasants, however, reduced to desperation by the fall in the prices of their crops, compelled it toward the end of the year to sanction a "no rent" strike. This movement under the leadership of Pandit Jawaharlal Nehru, a Brahman aristocrat but a convinced socialist, may foreshadow the eventual transformation of a nationalist agitation into an agrarian revolution.

This period of civil disobedience (1930-31) by aggravating the trade depression had devastating consequences for the Indian Exchequer. Twice it was compelled to raise loans in London. Salaries and the budgets of the social services were ruthlessly cut. The blow to the government's prestige was even more serious. The Congress overshadowed the government in the Bombay presidency, where it was strongest, and to a less extent elsewhere. Its flags, its colors and its cap were everywhere; bands of youths daily paraded the streets at dawn singing its songs; it could gather crowds of 40,000 persons at its demonstrations; its uniformed patrols acted as an unofficial police force in the bazaars, and no cart could pass through the streets unless the driver bore its certificate showing that he carried no British goods; its pickets sat all day before the shops and the saloons. The repression varied greatly from province to province, growing much severer in the later months of the year; but save in Madras it had little apparent effect. The offices of the Congress were closed, its property and presses confiscated and all its activities declared illegal. Yet its fly sheets were still distributed, meetings were still held, the organized boycott was never relaxed and its adherents rather courted imprisonment than feared it. The imprisoned leaders were well treated, but most of the 60,000 prisoners of the rank and file had to endure grave discomfort in the overcrowded jails. Even in the cities the police showed great brutality in beating with their *lathis* (heavy staves) demonstrators who passively squatted on the ground. In the villages with no white officers present the police in attempting to collect the taxes by beating faithfully maintained the age

long traditions of India which British rule has not eradicated.

While this struggle was at its height in the fall of 1930 the first Round Table Conference met in London (*Proceedings*, Cmd. 3778, 1931). Its British members represented all three parties. The Indian delegation included a dazzling contingent of princes, many able moderate politicians and the spokesmen of the Moslems, Sikhs, Christians and the depressed classes; but the Congress, which claims to speak for 85 percent of the population of British India and may in fact represent some proportion between a half and two thirds, was defiantly absent. Parliament could not concede less than the Simon report advised—provincial autonomy—but in that Indians took little interest, although all the main concerns of public life fall within the provincial sphere. Their demand was for self-government at the center, since only at the center in Delhi does India live as a nation. Could Conservatives and Liberals be induced to agree with the Labour party in granting a demand which after a transitional period must one day mean the virtual independence of India?

A new fact emerged in the first days of the conference which changed the whole outlook. The princes in speeches of surprising boldness flung their weight into the national scale and called for the inclusion of their states in an Indian federation. Here from the Conservative standpoint was an ideal safeguard. The princes are autocrats, the leaders of the landlord class and with perhaps four conspicuous exceptions unbending conservatives. Their fealty to the empire is moreover unimpeachable. They are tenants at will, whose thrones and honors depend on the pleasure of their feudal overlord. They may be and very occasionally are dispossessed for gross misrule, but in practise no difficult standard is imposed. Their oppressions and their employment of their revenues for personal ends are viewed with a tolerant eye so long as their political conduct is correct and their bearing deferential. The moment that federation emerged as an early possibility it was realized that the presence in the All-Indian Parliament of a princely contingent, which could not form less than a third of its numbers, would go far to neutralize the perils of democracy. Neither the Congress nor any other radical party could hope to dominate an assembly in which the princes would constitute one third and the Moslems another. It was perceived that the usual nominated official element might safely be sacrificed. The princes

would be no less reliable and they have the additional merit of possessing dark skin; they look like Indians. Their countrymen, on the other hand, who may see further into the future, were less discontented with the prospect than might have been anticipated. The princes may be merely "British officers in Indian dress" (to use Gandhi's phrase), but with them in turn the Congress hoped eventually to deal; they could not remain autocrats for ever.

In the light of this new proposal all British parties were prepared in principle to concede self-government to an Indian ministry, subject, however, to safeguards during a transitional period. The crux lay in defense. Without staff or artillery and with only a handful of junior regimental officers of Indian blood available at the start, it was evident that many years (not fewer, it was reckoned, than twenty) must pass before the native army could be entrusted with the defense of the peninsula. During this period the viceroy in his personal capacity must be responsible for the control of an army reenforced and largely officered by British soldiers, for the conduct of foreign policy and also in the last resort for finance. This last condition reduced the offer of "responsible" self-government to modest dimensions. In effect it meant a repetition at the center of the system of diarchy. The case for "reserving" finance was (1) that the cost of defense, the service of the external debt and the salaries of the covenanted civil service must be assured; and (2) that India's credit must be protected. For this latter purpose it was proposed to place the currency under the management of a central bank, which would in effect be a dependency of the Bank of England.

Indians of the moderate groups went surprisingly far in their reluctant admission of the force of this reasoning. They sought, however, to shorten the period of transition by urging that the Indianization of the army should be accelerated. They were prepared to accept some form of expert control over finance but objected to the supremacy of the City of London. It was further stipulated that the constitution must guarantee to all British subjects equality of trading rights with Indians. The exact interpretation of this principle has caused some controversy. India may not discriminate against British firms established in India but may do much to foster native industry.

Indians were disappointed by the limited range of the subjects which fell within the federal field. The princes would surrender nothing of

their present autonomy, with the result that the federal assembly was to exercise full responsibility over only a few matters of the first importance—notably customs, railways and posts. Within British India it could influence the salt tax and income tax and might enjoy concurrent legislative powers with the provinces over labor and some similar matters. Wide powers of veto were, however, to be vested in the viceroy. The members of the senate from British India might be indirectly elected by the provincial councils, while the chamber would probably be directly elected by an extremely restricted electorate, from which the mass of the peasantry would be excluded. The princes would nominate their representatives as they pleased. A supreme court was to be created. This sketch of the federal system could arouse no great enthusiasm when judged by its immediate effects; the keys of power remained in British hands. It did, however, promise a process of gradual evolution which should in twenty years yield full national self-government. The gain to India's self-respect was considerable; its present subject status would be ended within a generation.

The proposals for reform in the provinces excited little controversy and therefore little interest, yet it is in the provinces rather than at the center that the struggle against Indian poverty must be waged. The scope for constructive advance is on paper ample. It was proposed to place the whole range of provincial administration and legislation under Indian ministries responsible to elected councils, which should be able to move as fast as public opinion demands, in improving education and sanitation, raising the conditions of the industrial workers and fostering agriculture; they could even deal as they pleased with the basic agrarian problems of tenancy and land revenue and would have the police under their control. Indians underestimate these opportunities, but they have the right to answer that in practise the poverty of the exchequer will hamper their constructive work, and this will continue so long as a disproportionate part of the revenues must flow to the center to maintain a white garrison and an alien civil service. The franchise for the provinces was not settled, but it was proposed that between 10 and 20 percent of the adult population should have electoral rights. The latter percentage would enfranchise skilled workmen and the more prosperous peasants, but not the poorer tenants or the laborers. In the provinces also wide powers of veto were to be vested in the governor.

India had hoped little from the conference, but opinion grew less hostile as it proceeded toward its climax, a generous speech by Premier MacDonald in which he offered India peace and self-government. A few weeks later Gandhi was released, negotiated a truce with the viceroy and attended the second Round Table Conference, which assembled in September, 1931 (*Proceedings*, Cmd. 3997, 1932).

The second conference met with the British financial crisis at its height and was interrupted by the general election, which gave the Conservatives an overwhelming majority. Little progress was made, save over details of secondary importance; and the old difficulties, which the first conference had postponed, bulked larger than ever. The princes, now much divided, had become exacting over financial questions. From first to last the intractable jealousies of the religious communities overshadowed the conference, and the Moslems refused to take part in the hurried debates on responsibility at the center until their communal claims had been fully met. They insisted on the maintenance of the existing system of separate electorates. This the Hindus were prepared with reluctance to concede to them and also to the Sikhs, but they could not bring themselves to face the consequences in the Punjab and Bengal, where on the basis of population the Moslems would enjoy a small statutory majority. The result was that the Moslems then made common cause with all the other minorities. The grave new fact was that the spokesmen of the untouchables also demanded a separate electorate, which might include a population of forty to fifty millions, who would thus be permanently withdrawn from the Hindu community. This Gandhi stoutly opposed on the double ground that it would perpetuate the untouchability of the depressed classes by walling them off and that it was unnecessary since the Congress would provide for their adequate representation. Had he been willing to offer "reservation of seats" for their benefit, a compromise might have been reached. The worst aspect of this claim is that it would destroy the hope of creating any effective peasant or labor party in India, since the working masses would be split into three distinct electorates. Every proposal of compromise or arbitration failed, and the British government was left to impose its own solution. The older generation of Moslems, which alone was represented at the conference, had indeed little interest in Indian nationalism. By obtaining the separation of Sind from Bombay and

autonomy for the northwest provinces it secured a compact self-governing Moslem area covering the whole northwest. Some Moslems would prefer to make Islamic culture supreme within this great area—an Indian Ulster, as it were—and allow Hindu India to go its own way. The second conference, in short, served mainly to advertise the lack of unity among Indians. It was a matter for congratulation that it ended with an unambiguous renewal of the promise of self-government at the center no less than in the provinces by Premier MacDonald, who now spoke for a government representing an overwhelming majority of the British people.

The British government pursues, however, what its spokesmen describe as a "dual policy" in India; it reforms with a mailed fist. One hand waves the olive branch while the other wields the *lathi*; the total effect is not convincing. Using as justification a terrorist conspiracy in Bengal, which had assassinated several British officials, it placed that province under a severe coercive ordinance. It then extended the same coercion to the United Provinces, where there was no terrorism—nothing worse than a "no rent" strike of non-violent peasants. When Gandhi returned to India, uncertain whether he should continue to cooperate with the government, he sought an interview with the new viceroy, Lord Willingdon, to discuss among other things the effects of these ordinances. This the viceroy refused and thereby gave the signal, as the year 1932 opened, for a renewal of the struggle. The government continues, however, to work through committees sitting in India at the details of the Round Table draft which it hopes to embody in an act early in 1933.

This essay has sought to dissect by a rapid narrative the complexities of the Indian problem. It is manifest to all but a minority of Englishmen that their direct rule over a subject dependency cannot continue. It is no longer a question whether self-government is desirable; it is inevitable. India's will to freedom is fixed, and in spite of its military weakness it can render coercion costly, unprofitable and discreditable. It has indeed very much to learn. Only a minority of its population has yet begun to adjust itself to the modern world. It is probable that a native Indian administration will fall far below that of the British both in efficiency and in honesty. But a self-appointed teacher cannot with advantage continue his lessons while his pupils daily express their distrust. It is time to close a school when one must train machine guns on it to pre-

serve order. On the other hand, the tutelage under which India has been kept has been so tight that to terminate it without some period of transition would be a criminal act. India could not yet assure either its internal tranquillity or its external defense. So much all Indians know, yet the suspicion of the motives of this tutor, who has combined his trust with much profitable business, is so deep seated that it is difficult to reach agreement over the transitional arrangements. Indians understand only too well that Great Britain cannot but think of its own prestige, its investments and its trade, while it evolves schemes for their future welfare.

The other half of the problem is no easier. India contemplating a future of actual or virtual independence must create a consciousness of national unity over an area and among a population almost as large as those of all Europe with Russia left out. It must reverse the effects not of one conquest but of two. The Mohammedans are not yet wholly won for the cause of Indian nationality. They too have dark skins and have been made to feel their racial inferiority. But they also have their pride and reject that ancient persistent Hindu culture which is the ideal basis of Indian nationalism. A solution would have been easier some twenty years ago in the period when a liberalism imitative of the European still inspired the Indian movement for reform. Today two tendencies have declared themselves which it is difficult to reconcile with a constitution such as Indian liberals of the last generation would have hailed with gratitude. Gandhi's influence in spite of his humanitarianism represents a reaction to Hindu mediaevalism. On that plane Hindus and Moslems cannot unite. They could forget their differences only under the influence of some rationalist view of life. The Hindu tradition moreover has always been weak in the element of organization, and today it must organize on a continental scale. Again there is audible now, as there was not twenty years ago, the underground swell of proletarian unrest. The nationalist agitation may deepen into an agrarian revolution. India is an item in the world's distemper, and its fate may depend on the wheat prices that rule in Chicago. In the final analysis a further aspect of the problem appears. Lawyers can draft constitutions; only a dynamic group of men with wills and ideas can give them life. A great organized party with a sagacious social program could use the machinery of self-government to grapple with India's fundamental problem of village poverty. To achieve this it

is not enough to legislate; the villages must be galvanized into self-help. One party in India and one alone might in its erratic way do this, and that party is the Congress. But it seems that England can bestow freedom on India only by crushing the Congress.

INDICTMENT. *See* GRAND JURY; PROSECUTION.

INDIVIDUAL DIFFERENCES. *See* PERSONALITY; MENTAL TESTS.

INDIVIDUALISM is a modern word. The Oxford Dictionary finds the first instance of its use in Henry Reeve's translation of de Tocqueville's *De la démocratie en Amérique*, in 1840. Reeve in a note apologizes for adopting the term directly from the French because he knows "no English word exactly equivalent to the expression." De Tocqueville explains the meaning of the term thus: "*Individualism* is a novel expression, to which a novel idea has given birth. Our fathers were only acquainted with egotism. Egotism is a passionate and exaggerated love of self, which leads a man to connect everything with his own person and to prefer himself to everything in the world. Individualism is a mature and calm feeling, which disposes each member of the community to sever himself from the mass of his fellow-creatures: and to draw apart with his family and friends: so that, after he has thus formed a little circle of his own, he willingly leaves society at large to itself . . . individualism is of democratic origin, and it threatens to spread in the same ratio as the equality of conditions" (vol. iii, bk. ii, ch. ii).

The primary meaning of the word then is of a state or attitude of mind which is naturally produced in a certain kind of society. That society is most easily described in negative terms. It is one in which little respect is paid to tradition or authority. It is as far removed as possible from that primitive type of social organization where the overpowering dominance of tribal custom and tradition leaves little scope for individual initiative and concern and the members of the

tribe are so absorbed in the group that it forms what anthropologists have called a tribal self. More positively, an individualistic society is one where people "think for themselves" and are regarded as being "the best judges of their own interests," it being assumed that they have interests and business which are only their own. It is a society where "the movement from *status* to *contract*," which Maine regarded as the mark of a progressive society, has gone a long way.

Although such an attitude of mind may be characteristic of modern democratic societies it has existed before and is not so novel as de Tocqueville seems to imply. When Thucydides makes Pericles in the Funeral Oration say of Athens, "In our private intercourse we are not suspicious of one another nor angry with our neighbor if he does what he likes," he is describing the beginnings of individualism in this first sense of the word. The fifth century in Greece was marked by a great disintegration of tradition brought about, like individualism in modern times, partly by scientific discovery. As the Peloponnesian War increased this disintegration, Greek society was pervaded by an individualism so thoroughgoing that it is hardly distinguishable from egoism. This frame of mind is revealed at its best in the ideal of self-sufficiency which is an element in the Socratic character and which was taken up after Socrates and made into a way of life by the cynics. It shows itself in a less favorable light in some of the sophists of the end of the fifth century.

In the highly self-conscious society of that period attitudes were quickly expressed in theories, and Greece at this time offers the beginnings of individualism in a second and modern sense—a theory of the proper relation of the individual to the state. The Greek theories were concerned not with economic organization but with the more general question of political obligation. With this qualification, however, they were prototypes of modern individualist theories with respect to the relation of the individual to collective organization and his freedom from state interference. The text of the Greek theories was the contrast between nature (*physis*) and law or convention (*nomos*). Greek individualism foreshadowed modern individualism in that this contrast took two forms. The commoner form of the contrast in both periods is based on a belief in men's natural egoism. The social contract theory—the characteristic political theory of individualism—as put by Plato in the *Republic* into the mouth of Glaucon is in fundamentals

the same as the theory of Hobbes. Men by nature want to do injustice and not to suffer it. Finding the results of this state of affairs disagreeable, they make a convention neither to do nor to suffer injustice. Law is therefore an instrument for the benefit of selfish self-centered individuals. When it is not such it may be disregarded. So Callicles in the *Gorgias* contrasts the conventional justice of the law with natural justice, the right of the stronger. So also in the fragment of the sophist Antiphon legal justice is something added, a conventional rule which goes against nature. Such individualism is barely distinguishable from a theory of egoism. But in the second form of the contrast there are signs of another individualism which looks on law as cramping not the natural badness but the natural goodness of men. Thus Hippias the sophist is made to say in Plato's *Protagoras*: "All of you who are here present I reckon to be kinsmen and friends and fellow citizens, by nature and not by law: for by nature like is akin to like, whereas law is the tyrant of mankind and often compels us to do many things which are against nature." Some sophists attacked slavery as an unnatural institution.

There are also in Greek thought the beginnings of individualism in a third sense. In the *Laws* Plato connects with materialism those views which disparage law and the state, as he elsewhere connects them with sensationalism. Individualism, from a theory of what ought to be the relation between the individual and the state, becomes a metaphysic, the doctrine that the individual is a self-determined whole and that any large whole is merely an aggregate of individuals, who if they act upon each other at all do so only externally. It was no accident then that the most thoroughgoing moral individualism of the ancient world, the philosophy of Epicurus, based itself upon the atomism of Democritus. Epicurus was an individualist in his account of the relation of the individual to society. "There is no such thing as human society. Every man is concerned for himself." "Justice never is anything in itself, but in the dealings of men with one another in any place whatever and at any time, it is a kind of compact not to harm or be harmed." "We must release ourselves from the prison of affairs and politics." This moral doctrine was connected with a metaphysic which held that all things were made up of atoms—the Greek for individuals; that the variety of the world was accounted for by the composition and ordering of identical units. It

was bound up also with a psychological atomism which made the isolated sensation its unit and association and the desire for pleasure and aversion from pain its key to the explanation of mental phenomena. Further it is to be noted that Epicureanism was not naked egoism, although if it had been true to its materialistic basis it perhaps ought to have been. "Of all the things," says Epicurus, "which wisdom acquires to produce the blessedness of the complete life, far the greatest is the possession of friendship." Epicureanism, like much later individualism, starts with an intense appreciation of the voluntary and free relation of friendship in contrast with the compulsory and traditional bond of political and legal association; in order to justify this it emphasizes the free relation of contract and develops as a consequence of this one-sided emphasis on the freedom of friendship a psychology and a metaphysic which are really incompatible with the valuation with which it started. Thus in Epicureanism are found many of the elements which make up modern individualism: the view that society is nothing more than an aggregate of individuals; the doctrine that the state, law and justice are at best necessary evils; a scientific attitude of mind which leads to the acceptance of psychological atomism and hedonism; and a high valuation set on the voluntary association and the relation of contract.

To produce modern individualism two things especially were required: the enhancement of the idea of the supreme worth of the individual, which came from Christianity and blazed up again at the Reformation; and, secondly, the emergence of an economic system dominated by exchange. These two elements did not make modern individualism a more consistent doctrine. On the contrary. But they made it a more far reaching and pervasive doctrine. Religious individualism did not originate in Christianity, but it is not characteristic of earlier Judaism. The latter makes Israel—the nation, and not individuals—the concern of God. But with the downfall of national hopes there emerges in the prophets a new conception of the dealings of God directly with the individual. This finds most vivid expression in *Ezekiel* (xviii: 2-4): "What mean ye, that ye use this proverb concerning the land of Israel, saying, The fathers have eaten sour grapes, and the children's teeth are set on edge? As I live, saith the Lord God, ye shall not have occasion any more to use this proverb in Israel. Behold, all souls are mine; as

the soul of the father, so also the soul of the son is mine: the soul that sinneth, it shall die." Jesus in the Gospels takes for granted the direct relation of the individual with God. This is implied in the teaching of the fatherhood of God, and in such sayings as "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me" (*Matthew* xxv: 40). This religious individualism is quite unlike Epicureanism or even stoicism, for it combines a belief in the supreme worth of the individual with the teaching, "He that findeth his life shall lose it: and he that loseth his life for my sake shall find it" (*Matthew* x: 39). The individual who is of supreme worth is not isolated, but realizes himself in the service of the brethren. Individualism and socialism as ordinarily understood emphasize one or other of the two aspects which in Christian teaching are inseparable, and it would therefore be misleading to say that the teaching of the New Testament is solely religious individualism. But there is in the New Testament and in all Christianity the teaching of the supreme value of the individual, which is the great contribution to individualism. The end of institutions and social organization is to be found in their effect on the eternal destiny of the individuals. There is connected with this a doctrine of human equality, the basis of which is that compared with the infinite worth of human personality other differences, real and important as they may be, are irrelevant: "... neither Greek nor Jew, circumcision nor uncircumcision, Barbarian, Scythian, bond nor free . . ." (*Colossians* iii: 11).

The emphasis upon the individualist and the collectivist elements, which are both present in Christianity, has varied from time to time. The Reformation was an emphatic assertion of the individualist element which had been overshadowed by the authority of tradition and of the organization. The central doctrine of the Reformation was the universal priesthood of believers, a doctrine in implication individualistic and democratic. Luther himself did not draw the full consequences of his teaching of the "Liberty of a Christian Man," but those who followed him did—notably the Anabaptists, the Independents and the Quakers. Their religious individualism turned away from everything in organized Christianity which stood for the corporate and authoritative aspect of the church. Its implication was almost that "organized Christianity" is a contradiction in terms. The church is a fellowship of believers, each the

direct concern of God, each directly responsible to God, each guided by the illumination of God in his own heart and conscience. Hence there follow the doctrine of the inner light; the doctrine of religious equality, which makes the church the self-governing democratic congregation; the doctrine of the separation of religion and politics; and the denial that the law can make people good. Compulsory religion and compulsory morality both become contradictions in terms. Such religious individualism is a long way from Epicureanism, because it is not self-centered but God-centered. But when the religious faith which inspired it declines, its individualist principles tend to harden into egoistic individualism, although they often retain some element which only religious faith made possible. Utilitarianism, for example, retained a belief in human equality and a zeal for the welfare of others which from the point of view of the hedonistic psychology it had worked out were ridiculous.

This thoroughgoing religious individualism, most obviously exemplified in the Quakers, was held by only a small number; but its pervasive influence over all Protestant Europe and America was very great. Its denial of religious authority made necessary a new basis for political obligation in the principle that it is the concern of the state not to enforce a common standard of right action but to maintain a system of rights which are protected liberties. Because of its insistence on the absoluteness of conscience, the problem of modern political theory became the problem of how to reconcile the rights of conscience with political obligation. Hegel can scarcely be called an individualist, but he finds a place in the state for the individualistic element under the name of morality or the sphere of subjective individuality. He makes liberty the end of the state, and he makes the superiority of the modern over the ancient state to consist just in its finding room for this element. All modern political theory, except the theory of Bolshevism and of Fascism, is in this sense individualistic in that it seeks to find room for and encourage the individual moral judgment and is based on toleration and the maintenance of a system of rights. Most of the differences between modern individualism, strictly so-called, and socialism are differences within these common assumptions.

A second formative influence of modern individualism which must be considered before economic individualism is discussed is the effect of modern physical science upon social studies. The

rise of the modern sciences began with a repudiation of final causes, a return to atomism and a new emphasis on methods of quantitative measurement. The great prestige of the new physical sciences produced continuous attempts to apply their method to the study of man in his social relations. Such a scientific study of society will tend to treat individuals as independent units. Each will be regarded as an atom, something having its own nature complete in itself. If they are to be scientific units they will have to be atoms identical in qualitative character. Because the theory will be interested mainly in the laws of the combination of such units it will tend to regard the units as equal. Human equality is in one sense not a scientific doctrine. For scientific observation of men is bound to reveal their differences, and the supreme worth of human personality is not a scientific fact. But human equality may and did become the prejudice of a scientific method which is trying to apply the principles of the quantitative sciences to human affairs. The assumptions of scientific method thus confirmed a doctrine whose real origin was in religious and not in scientific individualism.

Hobbes was the first systematically to attempt to make political theory scientific in this new sense. His men are for the purposes of his theory identical, equal units. Because they are identical, their relations with one another are purely external. Their natures are not affected by the social relations into which they enter. This is the characteristic doctrine of what may be called scientific individualism. It persists in Locke, is abandoned by Rousseau and revived again by Bentham. Social and political relations are merely means by which the individual obtains more efficiently what he desired before he entered into those relations. The means may seem incompatible in temper with the ends for which they are advocated. Hobbes' men just because they know no natural restraint in their own nature have for the meager satisfaction of their selfish natures to accept a despotic authority in the state. Complete liberty thus has a way of turning into complete absolutism. But political and social relations do not bite into the natures of individuals. The individuals remain the same unchanged, spiritually isolated atoms.

The remarkable thing about this scientific individualism is that it failed as a theory of politics but had a noteworthy success in practical legislation and in economics. Modern political theory took its fruitful start not from Hobbes but from Rousseau, who was in spirit an individualist but

taught that men's moral purposes developed only in and with society. He thus revived the tenet of religious individualism that the individual finds himself only in as far as he devotes himself to something outside himself. The same principle is implied in Kant's distinction of the phenomenal self of mere inclinations and the real self which is found in the self-imposition of universal law. It was developed by Hegel and is fundamental both in T. H. Green's account of the nature of rights and in Bosanquet's doctrine of the general will.

In the main, however, English and French theory followed Hobbes' methods although it did not accept all his conclusions. The aim of the English empiricists was to found a science of human nature on the analogy of the physical sciences and therefore to apply the principle of atomism not only to society but to psychology and ethics. While for the purpose of society the individual is treated as a unit, for the purpose of psychology he is in turn regarded as a collection of psychological units—sensations or desires for pleasure and aversion from pain. Scientific individualism, like Epicureanism, bases itself on psychological atomism. The decisive steps in this analysis were taken by Hume, but Hume was not entirely a rationalist; he tempered his rationalism with a naturalism which found a place for sympathy along with egoism. Adam Smith followed Hume in this ambiguous attitude. He uses the hypothesis of universal egoism to explain the mechanism of exchange and the hypothesis of sympathy in order to explain the origin of governments. He exhibits therefore the double view of the harmony of interests which runs through Benthamism. He assumes in economics a spontaneous harmony of interests. "The study of [a man's] own advantage naturally or rather necessarily leads him to prefer that employment which is most advantageous to society." But politics is necessary because in other spheres interests are not naturally harmonious and need to be harmonized by the action of the law.

Hume's philosophy of association was sharpened in France in the hands of Helvétius into a strictly rationalistic and scientific doctrine and from him taken over by Bentham, the great exponent of scientific or, as it is sometimes called, radical individualism. Bentham was conscious that his task was to set up the study of society on a scientific basis and that therefore no facts were to be admitted which were not capable of clear definition and quantitative treatment. He imagined that psychological atomism and he-

donism would alone give him an account of human nature to which strict scientific analysis could be applied. Hence his elaborate defense of that conception of human nature which is implied in the economic man. But Bentham was not simply the calm investigator anxious to discover the scientific facts. Scientific analysis in the natural sciences had been the necessary means of man's mastery over nature. Bentham wanted a clear theory of human nature in order that as a law reformer he might know how to act upon it. He sees men as separate individuals seeking only pleasure and relief from pain. The pleasures and the pains they seek, like those who seek them, are qualitatively identical. Bentham asserted concerning individuals that each was to count as one and no one as more than one; concerning pleasures, that pushpin was as good as poetry. But although qualitatively identical, pleasures and pains can be quantitatively analyzed, compared and summed. The legislator observes in this aggregate of individuals seeking aggregates of pleasures diversities of interests, and his aim in legislating and in distributing punishments and rewards is to correct the disharmonies and by promoting an artificial identification of interests to produce the greatest happiness of the greatest number. The legislator himself is of course curiously different from those for whom he legislates. They seek their own pleasure; he seeks theirs. How in accordance with a general theory of psychological hedonism he manages to do that is, incidentally, hard to discover. Bentham and the Benthamites—James Mill, Joseph Hume, Francis Place and the rest—had an inborn zeal for reform. The theory gave them a clear simple view of human nature. With it they had a standard to guide them in reforming the cumbrous and antiquated contemporary system of law and government. It certainly needed simplification, and simplification was the starting point and goal of their theory. The psychology and the moral theory of utilitarianism, as this system was eventually called, have often been criticized. Psychological hedonism is an indefensible doctrine, and if it were true, utilitarianism would be untrue. For there is no passage from the fact that all men seek their own pleasure to the demand that they should seek the pleasure of the greatest number. But in spite of its defects this scientific individualism had far reaching consequences for English law and government, and for obvious reasons. From the point of view of the effect of legislation it does not matter whether the legislator thinks

that men seek pleasure or try to do their duty. If he makes it the aim of law to make men free to seek their own happiness as far as is compatible with others doing the same he will in effect be making men free to seek pleasure or to try to do their duty. Scientific individualism provided a simple and comprehensive theory by which a law which still tried to make people do what was right was transformed into a law which maintained a system of equal rights and sought to give all men the liberty essential to lead the good life. "Bentham," says Dicey, "was primarily neither a utilitarian moralist nor a philanthropist: he was a legal philosopher and a reformer of the law"; and his success in Dicey's view was based on the principles that "legislation is a science," that "the proper end of every law is the promotion of the greatest happiness of the greatest number" and that "every person is in the main and as a general rule the best judge of his own happiness."

The success of this legislation was not due to its scientific character to quite the extent that its adherents supposed. It professed to act on the general principle that men should be allowed to do as they like provided that they do not interfere with the liberty of others to do the same. But the law cannot really be so indifferent to what people like. A noise may be a nuisance although other people remain at liberty to make more noise: for what is wanted by the majority may not be liberty to make a noise, but quiet. Scientific individualism will not furnish a complete theory of legislation. Law has also to rest on the fact that there are certain kinds of behavior which most people in a community at any given time want to encourage or discourage. That implies some conception of a common good or the good life. The Benthamites failed to notice this, because they were typically middle class people promoting the legislation which the rising middle class wanted. They imagined that their principles were much more universalist than they were. It should also be noted that while scientific individualism did much good in legislation in extending the sphere of contract, its tendency to treat all human relations in terms of contract was an element of weakness. Not only did it produce an inadequate account of the state; it broke down also when applied to such voluntary associations as trade unions.

In legislation the radical individualists worked on the principle of the artificial identification of interests; in economics they assumed the natural identification of interests. The classical econo-

mists of the early nineteenth century accepted the utilitarian analysis of human nature and supposed that if the processes of free exchange were allowed to operate unchecked the greatest happiness of the greatest number would be automatically produced. This is less absurd in the economic sphere than it would be elsewhere. For economics is concerned with exchange, and exchange assumes that the exchanging parties have managed to identify their interests. The optimism of the earlier economists rests on the belief that, other things being equal, the division of labor and free exchange lead to an increase in happiness. The assumption is warranted although the optimism based on it is not, other things being so unequal. Nevertheless, scientific individualism seems to work better in economics than elsewhere. It is still largely the basis of orthodox economic theory. The reasons for this are to be found in the nature of the relation of exchange. Exchange is a relation in which A serves B's purposes and B serves A's purposes; neither party need be concerned for the purposes of the other although he serves them. Hence economics in its present form may be regarded as concerned with the efficient realization of purposes, the nature of the purposes being ignored. If it is regarded as the business of law in maintaining a system of rights to consider such restraints on liberty of purpose as are dictated by the good of the community as a whole, and to recognize the concern of individuals to act as their conscience dictates, then economics may be regarded in abstraction from ethics and politics, concerned as it is only with the efficiency with which purposes, if allowed by the state and approved by conscience, are achieved. This abstraction can most profitably be made so long as it is recognized that it is an abstraction. When it was made into a philosophy of social progress, as it was by the laissez faire school, disastrous results ensued and it was largely abandoned. For economic individualism as a general social philosophy assumes that individuals are equally free to make or accept a bargain, i.e. that the exchange is really free in the sense of "free and equal." But this is often obviously not the case. It presupposes an absolute instead of a relative separation between means and ends, as though the means chosen to achieve ends were not continually changing the ends. It ignores the amount of government and organization which is not contractual and which is involved in modern industry.

Economic individualism because it assumed

the natural and not, like political individualism, the artificial identification of interests failed in face of the conditions produced by the industrial revolution. Its one-sidedness easily turned the theory into its opposite. The theory meant to encourage freedom produced economic determinism. The labor theory of value, a theory originally meant to justify the distribution of property resulting from an individualistic economic system, became the central doctrine of Marxian socialism. The last great utilitarian, John Stuart Mill, largely abandoned scientific individualism whether in politics or economics. His *On Liberty* (1859) is a magnificent defense of the principle of religious individualism, of the supreme worth of individuality, although the political individualism in it, his attempt to find a principle determining clearly the limits of state interference, breaks down.

Individualism thought of as a thoroughgoing and consistent philosophy of social life necessarily breaks down. No one can really be an absolute individualist, any more than anyone can be an absolute socialist. For the individual and society interact on one another and depend on one another. Even religious individualists, who put the worth and value of human personality above all institutions, must recognize the part played by society and institutions in developing and fostering individuality. The history of ideas shows that individualism is infinitely fruitful so long as individuality is regarded as something to be achieved and realized. But if individuality is thought of, as it has been in many "individualist" theories, as something given and to be defended against attack, individualism loses its evocative force and becomes indistinguishable from egoism.

INDUSTRIAL ACCIDENTS. *See* ACCIDENTS, INDUSTRIAL.

INDUSTRIAL ALCOHOL is ethyl, or grain, alcohol rendered unfit for beverage purposes and made available tax free for manufacturing and commercial uses. Ethyl alcohol is second only to water in importance as a solvent and no substitute has been found for it in important chemical processes. Other alcohols, however, are also used industrially. Methyl alcohol, or methanol, or-

ganically the simplest of the alcohols, was known as wood alcohol because it was produced by the destructive distillation of hard wood; at present large quantities are synthesized from carbon monoxide and hydrogen. Its principal uses have been in the production of formaldehyde and as a denaturant. Butyl alcohol, or butanol, usually a product of fermentation but also synthesized, is important as a raw material of lacquer. Propyl alcohol and isopropyl are largely derived from petroleum. Amyl alcohol is manufactured principally from pentane, a gas secured from natural gas and from certain petroleum operations.

When alcohol began to be used commercially early in the nineteenth century the varnish and paint trades and lighting and heating were the chief sources of demand. The former are still the most important outlet in Great Britain, the latter in France. In the United States today alcohol is of comparatively little importance as domestic fuel, while the development of the organic chemical industries, the increased demand for toilet preparations and drugs and the indispensability of alcohol in laboratories and hospitals have vastly increased the industry's importance. The growth of the automobile industry, however, has created the greatest market for industrial alcohol. Nearly half the American production, which in 1929 equalled 100,000,000 wine gallons per year, is used as antifreeze solutions in automobile radiators; another quarter is required for cellulose solvents.

A vast potential demand for alcohol as a fuel has been stimulated by the increasing dependence of modern economic life on automotive transport. States deficient in petroleum reserves have experimented with alcohol as the most promising substitute for gasoline. The admixture of alcohol produced domestically is required in motor fuels in France, at considerable cost to the government agency, which sells it at a loss; "national" mixtures have also been used extensively in Germany, Czechoslovakia and elsewhere. In South America alcohol made at low costs from waste sugar products is used with ether produced from some of the same alcohol. The British dominions have developed such mixtures as nataline. Large scale experiments have been made with alcohol as a fuel in the United States, but the advantage will in all probability remain with gasoline as long as it can be produced at much lower cost. Industrial alcohol is slow in igniting and requires higher compression than the ordinary engine provides. Nevertheless, the recent perfection of a commercially

feasible process for producing anhydrous ethyl alcohol paves the way for greater use, since it has been found that a combination of gasoline and anhydrous alcohol is superior to plain gasoline as an airplane fuel.

Although there are many plants from which alcohol may be derived, there are relatively few economically profitable sources. Ethyl alcohol was formerly made almost exclusively from the starch in cereal grains; hence the origin of the name grain alcohol. In the United States corn, yielding approximately two and one half gallons of 95 percent alcohol per bushel, was the chief source. In Germany as a result of government policy in subsidizing agriculture alcohol is distilled mainly from potatoes which have been developed to a high starch content for the purpose. In Great Britain the Distillers Company, Ltd., representing the distillers of potable alcohol, who still employ chiefly grains, also controls the industrial alcohol field. There is a movement in France for greater utilization of surplus wine crops in the production of industrial alcohol, now chiefly derived from sugar beets, and considerable experimentation is being carried on with a view to discovering new plant sources in hitherto undeveloped regions of the world. In more recent years the cheap non-edible by-product molasses from cane sugar refineries, commonly called blackstrap molasses, has become the chief source of ethyl alcohol in the United States and in other countries where it is allowed free competition. Two and one half gallons of molasses are required on the average to produce a gallon of 95 percent ethyl alcohol. The manufacture of alcohol from plant sources is a simple process. Only fermentation, distillation and rectification in columns, all in a closed system, are required. By-products are carbon dioxide gas, which is either collected for sale or allowed to escape, and residues from which potash among other products may be recovered. Labor conditions are generally good and there are no special hazards connected with the industry. In 1929 an American plant began the synthetic production of ethyl alcohol on a commercial scale, using ethylene, a hydrocarbon by-product of petroleum refining, as the principal raw material. The success of the process is indicated by the plant's 1931 quota of six million gallons.

Although the alcohol industry is adapted to small scale operation the greater part of the supply is produced by large units, and there is close cooperation and financial integration between the alcohol and other chemical industries. The

United States Alcohol Company, which is controlled by interests of the Air Reduction Company, Inc., produces 40 percent of the supply of American ethyl alcohol. It helps, however, in the marketing of the competitive synthetic product of the Union Carbide and Carbon Corporation as well as the surplus of the Eastern Alcohol Corporation, a Du Pont subsidiary. It is perhaps due to the threat of synthetic alcohol that the company is broadening the production of its own manufactured alcohol brands, which now include lacquers, fertilizers, ether, nitrocellulose solutions and cellulose acetate as well as Stermo canned heat, Alcogas airplane fuel and Alcorub. The Commercial Solvents Corporation, the only commercial producer of butanol and an important factor in all the alcohol markets, is likewise connected with the Du Ponts through its joint ownership of a paint manufacturing plant with the Graselli Chemical Company. It recently sold an interest in the Resinox Corporation, a subsidiary, to the Corn Products Refining Company. In general, competition has relaxed since the introduction of the quota system by the Bureau of Industrial Alcohol.

The protection which various European governments have extended to the industrial alcohol industry has fostered the growth of nation wide marketing associations. Certain countries, however, have gone even further. In Switzerland the manufacture, import and sale of alcohol are a government monopoly. Imperial Russia monopolized its sale, and under Soviet administration its production and sale are of course a state function. France, which formerly subsidized the manufacture of industrial alcohol by means of a tax on all distilled spirits, has organized an office of national control to buy and sell all alcohol made from beets and molasses and to stabilize the entire alcohol market.

For many years taxation of alcohol has been a favorite means of raising governmental revenue. Egyptian historians have found what is claimed to be the first record of such a tax, initiated some five thousand years ago. England as early as 1855, however, realized the importance of the non-beverage uses of alcohol and undertook to make it available to industry tax free in the form of methylated spirits. Other countries soon acted to relieve their industries of what had become a discriminatory tax. The growth of the organic chemical industry in Germany led to an increased demand for ethyl alcohol as a raw material which had of necessity to be cheap and therefore tax exempt. The United States, last of

the industrial countries, legalized denatured alcohol by Act of Congress in 1906. Undenatured alcohol is available tax exempt in many countries for use in scientific institutions and hospitals and at times for use in certain industrial processes.

The United States government defines denatured alcohol as ethyl alcohol to which have been added such denaturing materials as render the alcohol unfit for use as an intoxicating beverage. Enforcement of the prohibition law complicates the situation without changing its essentials. There are two main types of denatured alcohol: completely denatured alcohol, which may be sold and used within certain limitations without special permit; and alcohol specially denatured so as to make possible its use—under federal permits—in a greater number of specialized arts and industries. The ideal denaturant not only renders ethyl alcohol unfit for beverage use, but once mixed with the ethyl alcohol it cannot be readily separated and it does not introduce elements incompatible with commercial use. Wood alcohol, or methanol, was the first denaturant because its boiling point is so nearly identical with that of ethyl alcohol that separation is difficult without elaborate distilling equipment. Methanol is, however, not suitable as a denaturant in the production of many fine chemicals and dyes, and a number of other substances have been used. In Great Britain pyridine has been extensively used as a denaturing agent and it has found some application in the United States. More recently special compounds derived largely from petroleum have been devised by the federal departments in cooperation with the alcohol using industries. In 1931, because of the deaths due to wood alcohol poisoning resulting from the diversion of industrial alcohol for beverage purposes, methanol was eliminated from the United States formulae and alcotate, a petroleum product, was substituted for it as a complete denaturant.

The permit system, operating as a function of the Treasury Department, formed part of the original prohibition enforcement procedure. Elaborately detailed regulations have been prepared and amended from time to time. The ninety odd manufacturers and the more numerous users are required to keep detailed records of their handling of alcohol; to furnish bonds for the performance of their obligations under the permit; and to secure basic and supplementary permits allowing the manufacture, possession, transportation or use, as may be the case, of such

specially denatured alcohol as their legitimate business requires. The system also involves inspection and supervision by federal agents of the observance of the regulations for the storage and use of the raw material and denaturants as well as of the distribution of the finished products.

Notwithstanding these precautions, the size of the supply made industrial alcohol attractive as a material which might be diverted into illegitimate channels. The fact that once it is completely denatured under federal supervision alcohol may be sold and distributed without the necessity of permits and records has at times complicated the problem and given rise to what have been known as cover up houses. Nevertheless, the growing cooperation of reputable manufacturers and users in the enforcement of the law and the increased efficiency of denaturants have caused those interested in this nefarious business to turn to the direct production of alcohol from readily available sugars and starches as a less dangerous, simpler and more profitable procedure. One of the evidences of cooperation has been the acceptance of quotas. The manufacturers of alcohol have agreed to limit production according to capacity so as to produce only the estimated minima required yearly by legitimate industry, thereby reducing a possible surplus production which might find its way into undesirable hands. The establishment of quotas is facilitated by the permit system, which enables the authorities to specify for what purposes the various specially denatured grades are to be employed and to estimate the quantities users will require. The Bureau of Industrial Alcohol of the Treasury Department has for years had the assistance of an Industrial Advisory Council, composed of representatives of manufacturers and users of industrial alcohol who serve voluntarily for the purpose of giving such advice and counsel as may be useful in the framing of regulations and increasing the effectiveness of federal supervision. It is believed that the diversion of industrial alcohol at the present time has been reduced to a comparatively negligible quantity and is of no special importance in the whole question of prohibition enforcement. According to the Wickersham committee the amount diverted in 1929 was between nine and fifteen million gallons.

The research devoted to the synthesis of the various alcohols in the last decade has resulted, on the one hand, in making available on a commercial scale alcohols which were formerly relatively rare and, on the other, in discovering

methods for the more economical production of such well known compounds as methyl alcohol. In 1930 for the first time the price of methanol fell below that of ethanol. The result has been a considerable competition among the old and the new interests for established markets. This has shown itself especially in the antifreeze field, where during the winter of 1930-31 substantial quantities of synthetic methanol were used. Although the United States Bureau of Mines, as a result of an investigation supported by manufacturers of methanol, declared that the product was harmless unless used as a beverage, its toxic nature led to serious consequences and special provisions have now been made for its distribution. The low prices of methanol have made it a possible substitute in some of the industrial uses to which ethyl alcohol has heretofore been put. Conditions indicate, however, that industrial alcohol also will be available for a long time to come at prices substantially below those which have prevailed. Improved technology has made possible a steady reduction in the price of ethylene, and this combined with improvements in the synthetic process gives promise of synthetic alcohol at a cost of production so low as to threaten the market for the fermentation product whenever the price of molasses rises above four cents a gallon. There is nothing to indicate that ethyl alcohol will not continue to be an industrial necessity. The manufacturer who must use it has been considerably harassed by the conditions incident to prohibition enforcement and would long since have turned to a substitute had it been possible to develop one.

INDUSTRIAL ARBITRATION. See **ARBITRATION**, **INDUSTRIAL**.

INDUSTRIAL ARTS relate to the production of articles primarily utilitarian in which the effort has been made to introduce aesthetic appeal. They reach their widest significance when their production assumes the proportions of an industry. The field in general is that of the industries producing goods for personal and household use and decoration, such as those concerned with clothing, textiles, jewelry, furniture, ceramics, glass, metal work and wall paper, and the printing industry.

It is usual to say that before the end of the eighteenth century, when production became largely a matter of labor saving machines driven by power, such goods were made by handicraft (*q.v.*) processes. Machines of one form or another, however, such as the loom, the spinning wheel, the helve hammer, the potter's wheel, the turning lathe and the printing press, appeared in some cases many centuries before the industrial revolution; power from wind and moving water was often made use of; quantity production and the division of labor had appeared to an important extent; and capitalist control was widespread.

Handicraft as a method of making artistic goods has its chief significance when it exists in connection with simplicity of producing organization and directness of contact with the consumer. In its simplest terms, outside of family economy, handicraft as an organized scheme of production appeared in western Europe as a system in which a master craftsman presided over a household unit consisting of one or more journeymen and apprentices. In this small unit the master craftsman was also a merchant dealing with his local community either through the manufacture of articles on order from individuals or by the sale of his products to retail customers. Under such conditions and such only craft work possessed and still possesses distinct and peculiar artistic possibilities. These reside largely in the opportunities afforded for individual expression, for the play of imagination and for experimentation, all favoring the de-

velopment of that rare individual, the creative artist craftsman. Even for less gifted masters this system brought the advantage of comment and criticism from customers, while daily experience effected an intimate knowledge of tools and materials, as to both their potentialities and their limitations.

These particular aesthetic possibilities were modified as soon as the origination of design was removed from the hands of the small master craftsman by methods of industrial organization aiming at greater quantity production or at least at greater measure of merchant control. When wholesale trade and distribution to markets outside the confines of the local community developed, the control of quality and design was transferred to the large master or merchant, and the craftsman, working with his hands, ceased to be an originator or creator. The results of such changes in the organization of production may have been good or bad artistically. The significant point is that when they took place aesthetic values were created by a method essentially different from that which characterized simple handicraft conditions. This shift in function, which is of great importance in the history of the industrial arts, began in western Europe at least three or four centuries before the industrial revolution and reached its highest point when power driven machines became the common instruments of manufacture. The separation of designer and maker persists to the present day and constitutes one of the chief obstacles facing improvement in the artistic standards of the art industries.

Examples both of standardized quantity production and of group workshops presided over by a single master or merchant are found in very early historic times. It is probable that group workshops produced the great numbers of glazed pottery figures and glazed tiles, so similar in artistic and technical character, which have been found in the tombs of early Egyptian kings, and also the delicate glass mosaics produced in great numbers at the time of the New Empire. The making of glass from raw materials is not a process readily accomplished by the individual craftsman. Special technical knowledge is needed and furnace equipment and control commonly beyond the resources of the single worker. There are other indications of group activities in the highly developed industries of Egypt. By the time of Herodotus linen yarn and cloth were exported from Egypt to neighboring countries in quantities so large as to suggest that their

production could have been compassed only in establishments of considerable size. From wall paintings and sculptured figures found in tombs we know that division of labor obtained in this industry.

Dyeing was early developed by the Egyptians, but it was the Phoenicians who excelled in this art. Tyre not only made cloth but imported it to be dyed and sent out again. So largely was the dyeing industry developed in Tyre in the first century A.D. that it was the chief source of wealth and made the city unpleasant as a place of residence. When one considers the trading genius of the Phoenicians it seems improbable that such a large manufacturing system was carried out on a simple handicraft basis, that is, with the craftsman acting also as a merchant selling directly to the retail consumer. It would seem almost inevitable that such an industry would be dominated by wealthy merchants who controlled groups of craftsmen in much the same fashion that appeared in western Europe from the fourteenth to the eighteenth century.

The Greeks were not an industrial people; handicrafts were despised as fit only for slaves and foreigners. War and government were the business of citizens. Preparation for war was consequently respectable, and the fact that Demosthenes inherited a sword factory employing fifty workers did not impair his standing in the state. Artistic work claimed some consideration, and exports of products of this nature formed a substantial item in Greek trade. The finest Greek vases of the fifth and fourth centuries B.C. were painted by artists whose creations were prized throughout Magna Graecia and Etruria and whose names in several cases are known today. On a black figured vase in the Alte Pinakothek in Munich there is shown an Athenian pottery establishment with a number of workers engaged in special tasks: two figures are engaged in throwing a large vase on the wheel, others are firing or stoking the kiln, while others are carrying fuel or unbaked pots; dominating the scene is the imposing figure of the owner or overseer.

In republican Rome there were large workshops producing in quantity. Many of these were on great landed estates in which industry was combined with agriculture and stock breeding. In the imperial epoch industrial establishments increased in size and number in various parts of Italy and Gaul. Some of these, producing great quantities of pottery, terra cotta vessels (many signed by individuals), lamps and even statuettes

for distant markets, were clearly in the field of the industrial arts.

The appearance of the quantity element in the making of goods designed for aesthetic appeal can be traced perhaps more readily and over a longer period in the history of weaving than in that of any other industry. This is particularly true if the study be confined to woven patterned silks which, being essentially expensive luxury products, exhibit greater variety and richness of design than other woven materials.

Of the conditions under which such silks were made by the Chinese in early periods little is known. It is only after silk weaving became domesticated in Persia that it is possible to learn something of the early practises of the industry. In the Sassanian period (222 to 650 A.D.) there is evidence that the art of pattern weaving reached a high point of excellence, and we know that it was during this time that Persian influence in this field, as in others, spread to Egypt, Syria and Byzantium. It was also at this time that Persian silks came into demand in Rome.

After the Arab conquest some light is gained on the organization of production. It was the habit of the caliphs to honor their favorites by gifts of choice robes of flowered silk, and the demand for suitable fabrics became so great that a manufactory for fine weaves was set up as an adjunct to the palace. Moreover it is on record that in the ninth century great numbers of workers were transferred from one of the weaving centers to Bagdad and there housed in a special quarter of the city.

Although rare examples of twelfth century fabrics show that Persian weaves had reached a high level of aesthetic quality, we know little of the origins of the designs. It is not until the appearance of the exquisite creations of the miniature painters and illuminators in the fifteenth century that the sources of woven patterns are made clear. The work of these artists was soon reflected in the products of the weavers, and the most splendid era of Persian silk design took on its abiding qualities. This inspiration continued throughout the sixteenth century. Rich brocades were added to the earlier, lighter fabrics, and the achievements of the weavers reached a splendid culmination in the production of superb and costly velvets. The glorious period of Persian textiles ends with the seventeenth century. At this date commerce demanded larger and larger supplies from the looms and the quality deteriorated, but by

this time Persian artists and weavers had set the seal of the national genius so unmistakably on all manner of silk fabrics that their conceptions have remained to the present day a major element in fabric design for all western countries.

During this long period of artistic ascendancy the creations of Persian weavers were the chief inspiration of the important textile production of Egypt, Syria and Byzantium and her subject provinces. From the sixth to the thirteenth century Byzantium was the chief world center of activity in all the industrial arts, and in the latter part of this period it was largely through the trade conducted by Venice with this city that the influence of Persian design reached the western world.

It was the crusades, however, that were responsible for the introduction of silk weaving into Europe. In the twelfth century a factory for silk weaving was established at Palermo by the Normans. As a result Sicily quickly became the chief European center for the production of fine fabrics. The most important cities of the Italian mainland soon followed this lead and from the thirteenth century onward Florence, Lucca, Milan, Genoa and Venice became active producers of woven silks. By virtue of sound workmanship and fine taste the products of Florence were so highly esteemed that they soon competed successfully with the silks of the East. The early stuffs were thin, light fabrics, such as sarcenet and taffetas, which followed the earlier designs of Persia or Persian quality as transmitted through the fabrics of Syria or Byzantium. Later came heavier satins, damasks and brocades and finally velvets and cloth of gold.

In all these materials the eastern influence, particularly that of Persia, is in strong evidence. Patterns were either copied or modified from the oriental weaves and show little mark of the creative designer. It is not until the sixteenth century that a distinctly occidental quality becomes prominent. At this time Italy was flooded with engravings of ornament designed by artist decorators. The inspiration of these engravings, which were commonly collected in book form, was of course classic rather than oriental. They reflected the current fashions in ornament and showed elaborate designs of panels and friezes, trophies and cartouches. Their influence, together with contemporary paintings, dominated the fabrics of the high Renaissance. Another type of engraving of the sixteenth cen-

tury exerted an influence upon the character of Italian woven patterns. These were books of designs for embroidery printed for the use of "noble and virtuous ladies," who apparently spent much time in the decoration of fabrics intended for altar cloths and church vestments, for hangings for the home and for their own costumes. Guilmarde gives the names of twenty artists who published such books.

It is through such channels that the Italian Renaissance impressed itself upon the patterns of textile fabrics, and although we cannot trace the names of the fabric designers who adapted the patterns we can see clearly the sources upon which the weaver depended. The published engravings accomplished at least one thing: they put on record for the first time the names of designers as a class. The reason why these particular names have survived in printed form rather than those of the more humble fabric designers lies mainly in the fact that the Italian engravers of the sixteenth century strove to cater to the wealthy and aristocratic classes. Along with flat ornament their books or sets of engravings almost invariably include elaborate compositions for *fêtes galantes* and triumphal arches and architectural decorations. Their ambition was to join the high company of the architects and to be classed at least as talented decorative artists worthy of important commissions.

As to the conditions under which silk textiles were produced in Italy, it is evident from the history of the Florentine guilds that the merchant entrepreneur early became a dominant figure. Merchant guilds and craft guilds existed side by side in the twelfth and thirteenth centuries, but in the fourteenth century silk merchants and silk weavers are found enrolled in the same guild. The development of the export trade at this time gave the wealthy merchants a leading role and they gradually became wholesale merchants controlling many establishments of home workers, to whom they supplied materials and tools and probably designs.

From this picture it is evident that the domestic system of production gained an early start in Florence and also probably in other industrial cities of Italy. These developments, particularly in those trades dealing with luxury products, were followed soon afterward by similar manifestations in France, Flanders and England; and by the fifteenth century the transition in industrial organization that witnessed a constantly increasing control of production by the wealthy merchant class was fairly begun.

The continuation of the story of silk quantity production is found in the city of Lyons. In 1450 Charles VII granted to this city a monopoly of the silk industry in France. This resulted at first merely in the development of a trade center for Italian merchants, but by the sixteenth century, largely from the settling of Italian weavers who had fled from Lucca and Florence because of political disorders, many weave shops were established and the silk industry assumed large proportions. The conditions of silk production at Lyons in the sixteenth century afford a striking example of what was to develop more slowly in other industries and other localities. The town was free from the guild regulations that still prevailed in other places. There were no regulations as to apprentices or journeymen or hours of labor. There were no restrictions as to the number of looms a master might own or control, and there was freedom of contract as to rates of payment of employees. These conditions quickly resulted in a large volume of production under merchant control, a highly developed example of capitalist organization under the domestic system.

Up to the middle of the seventeenth century the designs were largely representative of Italian influence; but as pattern weaving became well established and the national genius increasingly asserted itself, distinctive French taste began to appear in the products of the looms. From this time until the fall of the monarchy the weavers of Lyons exerted every effort to meet the demands of the luxurious French court for exquisite and extravagant silks. Talented artists, like Pillement and Philippe de la Salle, were called upon to supply novel and fanciful designs and all the technical resources gained in six centuries of experience were utilized, with the result that the art of figured silk weaving reached a level never since surpassed.

The industrial changes engendered by advancing commerce are obvious in other art industries as well as in silk weaving. The making of glass in Venice became so important an industry that from the thirteenth century its manufacture was supervised by the Venetian government and the workers were segregated on the island of Murano in order to guard the secrets of manufacture. From this time on production continued under factory conditions, although only simple hand processes were used. The trade brought the city a tremendous business with the whole contemporary world. As glassmaking methods improved, the state became so zealous for its trade that it

imposed the death penalty on any craftsman who carried abroad the secrets of manufacture. The finest work was produced in the fifteenth and sixteenth centuries and by the beginning of the eighteenth—before the invention of machinery had touched the industry—its heyday was over.

In France the early guild regulations centering about the rights and privileges of the individual master craftsman continued in force through most of the eighteenth century. The making of French furniture during the seventeenth and eighteenth centuries presents typical conditions. In this trade the rules for apprentices and journeymen continued to be rigorously enforced and the right of sale confined to those who had been admitted to the corporations as masters. As a result furniture continued as a rule to be made in small shops presided over by a master craftsman. On the other hand, the critical need for designs calculated to make the strongest appeal to the taste of a sophisticated court under each ruling mode led to dependence on artists outside of the workshop. This dependence is first evidenced in the sixteenth century when the new fashion of the Italian Renaissance was set by royalty. During the fifteenth century the decorative alphabet of the *huchiers* was derived from the Gothic traceries, carvings and moldings of the cathedrals and churches within their common view. Of the new style they had little understanding, and it was not until the middle of the sixteenth century, when Jacques Androuet du Cerceau published his engravings of furniture based on Italian motives, that a consistent expression of the new order was possible in furniture. These engravings of du Cerceau were a veritable encyclopaedia of decorative motives, and when circulated throughout France they became rich source books for the guidance of the cabinetmakers.

In the reign of Louis XIV the relation of the artist designer to production stands out in even clearer relief. Beginning with the voluminous engravings of Jean Le Pautre, which supplied many grandiose motives for the early phases of the *style Louis Quatorze*, and continuing with those of Jean and Daniel Marot, Jean Berain, Pierre Le Pautre and Nicolas Pineau, we find the record of much of the source material upon which the cabinetmakers fashioned their products during the long reign of the *Grand Monarque*. For the most part furniture continued to be produced during this period in the shops of small masters, but exceptions to this rule are found in the case of those installed in the

Louvre and favored with the patronage of the king. Such fortunate individuals were exempted from the control and regulations of the corporations. Foremost among *ébénistes* thus honored was André-Charles Boulle, who produced a large share of the most important cabinetwork for the court during the entire reign of Louis XIV. Apparently Boulle himself designed many of his productions, but it is certain that he employed the designs of others, notably Jean Berain and Pierre Le Pautre, in his later work. In 1720, when Boulle's plant was destroyed by fire, it represented a considerable establishment comprising besides his four sons no less than two *menuisiers*, eighteen *ébénistes* and six *ciseleurs*.

Throughout the reigns of Louis XV and Louis XVI a notable line of decorative artists played a leading role in the design of goldsmith work, tapestries, carpets, mirrors and furniture. The character of these artists ranges from versatile and broadly equipped architectural decorators like Just-Aurèle Meissonnier and François de Cuvillies to specialists like Ranson and Lalonde of the later periods. The large output of elegant furniture made by Jean Henri Riesener for Madame du Barry and for Marie Antoinette is evidence that large workshops continued to be the rule during this period with *ébénistes* patronized by royalty. The case of David Roentgen still further illustrates this situation. Coming to Paris at a time when German cabinetmakers were in favor, he became *ébéniste* to Marie Antoinette and at the same time maintained his extensive workshops at Neuwied from which his furniture went to many courts in Europe.

Quantity production of artistic goods by handicraft processes was not limited to the West. Many cases can be observed in the Orient where the inevitable results of exceptional demand are found in concentration of workers and division of labor. In a letter written from China in 1722 the Jesuit missionary Père d'Entrecolles gives an elaborate description of the manufacture of porcelain in the imperial factory town of Kingtehchen. He states that within the walls of the town an infinitude of artisans and artists live and work and furthermore that before a piece of porcelain leaves the furnace it passes through the hands of more than twenty persons, each performing a distinctive task. Finally the object goes to the painters, each of whom is a specialist confined to one of seven kinds of decorative treatment.

In northwest India, where rugs have been produced in large quantities for several centuries,

there exists today a peculiar example of modern commercial manufacture under craft conditions. At Amritsar there are several establishments in which large carpets are made in the old manner on orders from western capitals according to designs furnished by the purchaser. These designs, accurately drawn and colored, are based to a large extent upon splendid reproductions widely available for the last half century of rugs exhibited at the Welt-Ausstellung held in Vienna in 1873.

The industrial revolution changed radically the quality of industrial art by substituting mass demand based on low cost as the factor controlling production in place of the sophisticated and luxurious standards of a court and aristocracy. It also substituted the impersonal market as the goal of the manufacturer in place of the individual consumer whose satisfaction was the ideal aim of the craftsman. In this new world of the factory the designer became a mere workman engaged to give salable form to the products of the machine. To increase the sales appeal the manufacturer, without vision to comprehend that functional service and simplicity of form were the natural opportunities for the machine, concentrated his efforts upon decoration as the feature best calculated to attract his new public.

The decadence involved in a half century of production based on these objectives was presented to the world at the Crystal Palace exposition of 1851. It is safe to say that no such collection of atrocities had ever before been assembled in the name of art. Important reactions came from the exposition, however; on the one hand, it brought strikingly to the minds of statesmen and public alike the great importance of industrial art as a factor in national wealth and, on the other, it revealed a depth of artistic decadence in this field that made a profound impression upon persons of taste not only in England but throughout Europe. From this time on cultivated amateurs, some of whom had been stimulated by the romantic revival of previous decades, turned more earnestly to the collection of examples of applied art from the older periods. This tendency gained impetus and authority from the Empress Eugénie's passion for simulated eighteenth century furniture and decoration. In the decade of the 1860's this interest in the art of the past had become so strong that in both western Europe and the United States it reacted upon the manufacturers, who began to seek motives for production in the earlier period

forms. The first results were crude and tasteless; but as exact knowledge of historic examples increased through publications and museum collections, the quality of the manufactured product gradually improved.

This dependence of the manufacturer upon forms from the past, whether it issues in mongrel adaptations of inexpensive machine made furniture or in fine reproductions in which handwork is an item, has continued to the present day. Aside from the fact that this practise has stultified the designer in any creative attempt to develop industrial art in forms expressive of the spirit and needs of our own times, it has the great weakness of feeding the machine with forms appropriate only to the craftsman. For the craftsman ornament is a natural attempt to add further beauty to his product, but exact reproduction of ornament in endless repetition by the machine is inherently distasteful.

The only creative note in the third quarter of the nineteenth century was sounded by William Morris. Viewing the machine and commercialism as the cause of the artistic degradation of his time, he set forth valiantly with his colleagues to turn back to the Middle Ages for both processes and inspiration. Morris had little feeling for functional design as related to useful objects. His genius found its expression mainly in the decorative treatment of flat surfaces and reached its highest achievements in designs for wall papers and cotton prints and the exquisite pages issuing from the Kelmscott Press. His superb talent for composition, his emphasis upon pure color and the serious study of natural forms brought new expressions of beauty to his contemporaries; but his ideals took no account of the real aesthetic problems of his times and he accomplished little or nothing to lead industrial production out of its aesthetic morass. As a result of his teachings and example, however, the English arts and crafts revival began to take form about 1875. This movement, which attracted much attention for a score of years, relied upon a return to craft methods and upon a return to nature for inspiration in design. It engaged the enthusiastic devotion of many talented individuals but made only a slight impression upon mass production.

Decorative treatment, this time mainly of line and silhouette, was the aim of the artists assembled in the 1890's in l'Établissement Bing in Paris to create "l'art nouveau." Some charming pieces of furniture were created but, depending as it did upon a decorative motive, the move-

ment collapsed as soon as this motive was travestied and cheapened by inferior designers.

It was not until the recent appearance of the "modern" movement in applied art that a new emphasis led the way toward a sounder basis for mass production design. This movement, which has developed a vigorous growth in Europe in the last thirty or forty years, has as yet met with little appreciation in the United States. Its genesis in Europe came from craft workers aiming to create forms more suitable for modern living conditions and more expressive of modern taste. The qualities that have characterized its best manifestations in three-dimension objects are fitness for service in present day living conditions and appropriate use of all materials made available by modern industry, with reliance for aesthetic effect upon good proportions, fineness of line and surface qualities of the material itself instead of upon painted and plastic ornament. These qualities, emphasized by European craftsmen in ceramics, glass, wood and metal, are obviously those peculiarly fitted for machine production. During the last few years, beginning in Germany, there has been incorporated in the modern movement the logical and essential idea of designing directly and purposefully for the machine. It is in the combination of these two phases that the modern movement achieves its real importance, inasmuch as it is obviously only through such a program that both low cost and attractive quality can be secured for the mass of the people.

Designs for the machine that are notably successful as regards line, surface and even color are illustrated by fine modern bathrooms and kitchen sinks. In these cases rigid attention to functional requirements has been made possible by modern technical processes. The same success has been increasingly reached in the case of the automobile and in fact with most of the things that have come into being in the industrial age with no traditions of craftsmanship behind them.

Examples of inexpensive table glass have of late achieved unusual fineness of outline coupled with pleasing notes of color, and silver flatware from several establishments has taken on forms of extreme elegance in designs thoroughly appropriate for machine production. Table china of the middle range has attained high excellence in form, although still for the most part cheapened by petty decoration and realizing little of the color and texture effects possible solely through glazes and body quality. Sim-

plicity of form dictated by purely functional and technical considerations has, however, found only moderate approval in the matter of furniture. In this field emotional satisfaction has not always accompanied rationalization. This situation well illustrates the major problem involved in the mass production of industrial art.

Present tendencies give promise of improvement, but in the United States at least it is evident that substantial progress will be a matter of considerable time. Such progress needs a new mental attitude on the part of both producer and consumer, and this will develop only slowly. It needs a growing appreciation on the part of the consuming public of the dignity and simplicity of straightforward design in household goods in contrast to mere decorative prettiness. It needs more courageous and intelligent recognition by manufacturers of the tendencies and resources of the machine age in place of dependence on traditional forms, and it needs finally the highest talent in design. This last essential will be assured only by a fuller recognition of the function and importance of the designer in mass production. This function is very different from the conception of the nineteenth century, which regarded the designer merely as a decorator. The twentieth century calls for much more fundamental and far reaching abilities. If the designer is to make important contributions to the new order he must possess, in addition to creative ability and sensitiveness to line, form and color, a thorough knowledge of materials and technical processes not only from the mechanical but from the economic side. In other words, he must have mastered the machine as a tool and through such mastery make possible the production at low cost of useful things that will fulfil all the demands of service and at the same time be capable of conveying high satisfaction to the spirit.

One of the factors that have operated to hold back improvement in the industrial arts has been lack of legal protection of designs. This is particularly true in the United States, where such protection can be secured only through a design patent which requires months to obtain and is expensive when large numbers of designs are involved. Under such conditions the inducement for the manufacturer to seek creative work and to pay the price it demands is greatly reduced, as in certain industries a design is hardly placed on the market before it is copied. The Vestal Design Copyright bill, which was considered by the Seventy-first Congress (1930-31),

provides for immediate protection as soon as an adequate representation of the design is sent to the copyright office. Its provisions are limited to five classes of products: textiles, lace and embroideries; furniture; lamps and lighting fixtures; footwear; jewelry and articles made of precious metals. The bill was not passed by the Senate, and although the subject has again been brought up in Congress no action has yet been taken.

INDUSTRIAL DEMOCRACY. The term industrial democracy was coined as far back as 1897 by Beatrice and Sidney Webb to describe the workings of democracy within the trade unions themselves. They traced the evolution of trade union democracy from the primitive forms within the small local union to the complicated forms of representation developed within the national unions; this representation protected the membership on the one hand from the sectional selfishness and the lack of experience of the local units and their leadership and on the other from the concentration of authority, which inevitably passed into the hands of the national officials as the process of collective bargaining expanded to include wider geographic areas and the greater range of items resulting from encroaching workers' control or new industrial techniques. The Webbs did not, however, carry over the concept of democracy from trade unionism to the industrial relations between employer, worker and the community.

In the decade before the World War the movement for democratic control within the trade unions, especially in England and in Germany, exhibited two diverse tendencies. On the one hand, there was a rebellion against conservative leadership both national and local in the more strongly organized national unions, often taking the form of a demand for local autonomy and decentralization. Thus in 1905 the German syndicalists called themselves *Lokalisten*. On the other hand, the Industrial Democracy League of the South Wales miners stressed the need for the creation of a national body, a national agreement, the curtailing of the power of local officials and the creation of representative delegate rank and file committees and boards to replace the separate sectionalized organizations which weakened mine unionism in Great Britain. In time, however, these two forms merged into programs for industrial unionism, syndicalism or guild unionism. In these left wing movements and in socialism "democratization of industry" soon took on a somewhat broader aspect than mere collective bargaining, but it was used synonymously with public control or socialization. As the influence of the Russian Revolution made itself increasingly felt in other countries, the extreme left wing of the labor movement dropped the "bourgeois" concept of democracy and substituted a forthright demand for workers' control.

The term industrial democracy was adopted during the war to cover innumerable types of program for joint industrial relations in both

Europe and the United States. The governments of Norway and Sweden appointed commissions to investigate "industrial democracy" with, however, a definite connotation of socialization.

The vogue of the term was particularly pronounced in Great Britain and the United States. In his *Aims of Labor* (London 1918) Arthur Henderson defined it as the demand for "the progressive elimination from the control of industry of the private capitalist, individual or joint stock, and the setting free of all who work . . . for the services of the community." A similar interpretation was placed upon it in the United States by the League for Industrial Democracy, essentially a university socialist organization. To Samuel Gompers and to American trade unionists industrial democracy had the more limited definition: "The old political democracy is the father of this new industrial democracy; the trade union is the potential new industrial democracy."

But it remained for American welfare capitalism to place an interpretation upon the term well in accord with its individualistic, laissez faire philosophy. During the World War industrial democracy connoted a scheme of arrangements to avoid labor disputes which might interfere with the production of munitions and other necessities in a period of labor shortage. Employee representation schemes, based mainly on collective bargaining with unions or at least not antagonistic to the development of unionism, were encouraged in the key industries, many of which had been devoid of any labor organization before the war. After the war emergency had passed, most of these industries cast off lip homage to unionism and employee representation and company union plans emerged. Their purpose was to defeat unionism or at best they were concessions in the form of limited representations, recognized as necessary because of the increased size of plant working forces and as aids for the more effective enforcement of plant policies, while at the same time eliminating "interference" by trade unions. The term industrial democracy was reserved for a particular type of employee representation, in which organization of the company union was patterned after the government of the United States; the bulk of the workers in the plant constituted a house of representatives, the supervising and technical staff a senate and the owners a cabinet. Although measures for "democracy" might originate in either of the houses, the approval of both was needed, and the cabinet held the veto power. The for-

malism of the scheme was equaled only by its inadequacy and there now remain only a few instances of this type of company union. In 1919, however, the term was still fashionable in employers' groups; the New Jersey Chamber of Commerce called its series of conferences a discussion of "democracy in industry."

More recently in his *Industrial and Political Democracy* W. Jett Lauck makes collective bargaining one of the essential bases of industrial democracy and by that criterion rules out most of the schemes of employee representation in operation in the United States. How vitally he differs, however, from the European advocates of industrial democracy is shown in his inclusion, as another basic point, of employee stock ownership (if it bears full voting powers), profit sharing and the like. While it is true that his concept of democracy recognizes encroaching financial control or co-ownership as a factor, it more nearly resembles isolated producers' cooperative schemes than the Hendersonian ideal of socialization. Its fulfilment is limited to "primitive democracies," like the Columbia Conserve Company, and it cannot be applied to the large corporation or to industries as a whole. It therefore offers no fundamental challenge to the basic financial structure of capitalist industry. Its progressivism moreover is limited by the American industrial scene; it views collective arrangement plant by plant and only in rare instances where unionism is in its control is its scope national even for a single industry. There is no connecting link between industrial and political democracy and both remain within a modified laissez faire organization of society.

By contrast, in Germany, where the movement for industrial democracy has been revived perhaps to rival the challenging communist dictatorship of the proletariat and workers' control, the term has been extended from plant and industry to a comprehensive scheme of national industrial relations. The emphasis on industrial democracy derives from the failure of the present organization under governmental provision of works councils to provide for a national body integrating and making comprehensive the plant and industrial councils and providing for them the industrial statesmanship, especially on the workers' side, which would correct the weaknesses of plant and local bodies. As in the miners' movement of Great Britain, it bears as a corollary the democratization as well of trade union government. The governmental compulsory provision for works councils, however, suggests

that this type of democracy is not separate from and parallel to political democracy but an integral link between the community as represented by the government and economic organization. Industrial democracy of this caliber is not synonymous with but rather preparatory to socialization, of which it is a limited form.

INDUSTRIAL DISEASE. *See* INDUSTRIAL HAZARDS.

INDUSTRIAL DISPUTES. *See* LABOR DISPUTES.

INDUSTRIAL EDUCATION is the systematic and institutionalized effort of society to promote by educational methods the adaptation of its members to the changing conditions of livelihood activity. Since the industrial revolution increase of population, geographical extension of commercial and industrial relations, increase in size and complexity of organizations and in specialization and division of labor, mechanization with accompanying rapid change in industrial technique, and the increasing functional distinction between ownership, management and labor in capitalistic society have complicated the conditions of individual fitness and adjustment and have compelled social recognition of the need of more organized effort to promote adjustment. Present common recognition of this need may be traced to the development within the field of education of the doctrine that education is primarily a process of preparation for an adjustment to life's activities and only secondarily a process of acquiring information; to the

growth within industry of a belief that it can diminish production costs and strengthen its competitive status particularly in foreign trade by training more efficient labor; and to governmental recognition of the political and economic advantages of well trained workers.

Industrial education as conceived in the twentieth century is an evolution from simpler, less socially conscious forms of preparation for livelihood in earlier industrial societies. Leaving out of consideration minor transitional aspects, it was preceded by the autonomous and the institutionalized apprenticeship systems. The autonomous apprentice system was characteristic of families, clans and tribes in early societies, in which the individual was introduced into the group culture by the activity of living itself. In the home and on the land father or neighbor taught the youth from earliest childhood the skills essential to survival in the culture of the group. This form of effecting adjustment still survives among some peoples of Asia, Africa and South America and even in some isolated spots of the industrialized countries of Europe and North America. As early man raised his standard of living beyond mere subsistence and particularly as differentiation among crafts appeared and trade developed, these autonomous methods of induction to earning livelihood also became more differentiated and formal and apprenticeship became institutionalized. As early as the Babylonian Code of Hammurabi (2100 B.C.) apprenticeship commanded state attention. The institution survives even today, although in an atrophied form, as part of the European system of industrial education and through collective agreements between organized employers and workers in some industries in the United States.

Technically the system was suited to industry based upon crafts. The economy of indenturing a youth to a master and of a subsequent period of journeyman wandering and contact with other masters derived from two primary facts: that power in processing was essentially human power, the tool or machine being but an extension of the human muscle; and that the existing body of craft technique in applying power and skill was unrecorded and could best be acquired by personal instruction and practise under the eyes of a master. Most of the survivals of apprenticeship in industrialized societies are in the industries that still utilize muscular power and craft technique, such as construction, printing, machine repairing and art products. Apprenticeship as a general and exclusive system of adjust-

ment of youth to livelihood activities lost its social usefulness when science and invention discovered how to utilize other sources of power than human muscles and built up an analytic record of craft skills and of laboratory discovered methods before unknown. The mechanization of industry and increasing division of labor which began with the nineteenth century had so developed by the end of that century in western Europe and the United States that a new problem of adjustment of the individual to industrial requirements had emerged.

The first reaction to mechanization of industry was, on the part of parents and youths, to the view that lengthy personal instruction was superfluous for the relatively simple operations of machine tending and, on the part of employers, to the view that untrained youths were sufficiently competent and were cheaper for ordinary factory operations. Apprenticeship began to decline and apprenticeship legislation was gradually repealed in order to render more simple the acquisition of labor by the rapidly developing factory industries.

It was in Central Europe, where the apprenticeship system survived longest, that industrial education typical of today had its beginning. A political rather than an educational impulse led Germany to become a pioneer in modern industrial education, as it leads Russia today to the development of a newer, broader and more integrated system of cultural-industrial education. The response of Fredrick William to Napoleonic victories, "The State must regain by intellectual power what she has lost in material power," fixed in the German mind the ideal of power through education, and the ambitions of the newly created empire following the Franco-Prussian War led to an elaborate system of industrial education which was largely supported and directed by the state. There are higher schools for those who are to become managers, middle schools for those who are to become assistants and foremen and a great variety of schools for the training of skilled workmen.

Two characteristics of the German system of industrial education are noteworthy. In the first place, there is little individual freedom of choice and change of occupation. While a youth is still in the common school his parents must decide, in terms of course of their own financial capacity to support him while studying, the *Stand*—social status and trade—which he is to have; and subsequent education is directed toward training him for that *Stand*. In the second place, appren-

ticeship is an important element; formal schooling is not a substitute for it but a supplement to it. Although the industrial schools are differentiated as to trades, the emphasis in most of them is not primarily on trade technique, which is largely left to shop work during apprenticeship, but major attention is given to training in the arts and sciences pertinent to the trades and to citizenship.

England, where as late as 1870 schooling was neither compulsory nor gratuitously provided by the state, has given more attention to general elementary education than to industrial education. Since 1900, however, there has developed a fairly substantial system of industrial education, in which an important element is voluntary evening schools for factory workers. Although these schools are aided by the state, there is almost no state direction of their administration but the workers themselves have taken the initiative in their development. They are not so specialized as the German and have not received the approval of labor unions for teaching craft and machine processes, but they supplement factory experience with an effective practical emphasis on principles and theory.

In France educational effort on behalf of industry has been centered principally on higher schools for the training of technicians and executives. For the training of workers apprenticeship unattached to an organized system of industrial education continued in practise much longer than in the other major countries. This was due to the diversity of French industry, to the style and quality of its products, which make craft skill important, and to the absence of any general tendency toward mechanized quantity production. As early as 1880, however, there was beginning to be recognized a breakdown of the apprenticeship system, and this breakdown was accelerated by the World War. Since 1919 laws have been passed looking toward the development of a system of industrial education, but preoccupations with reconstruction have delayed their effective application.

In colonial, semicolonial and oriental countries industrial education is receiving pioneering attention, but while significant to the regions concerned the results are meager. In those regions settled by Europeans the economy is still one of exploitation and development of basic industries and compelling problems of industrial education have not emerged. In oriental countries educational efforts are concentrated chiefly on problems of general primary and secondary

training and on the beginnings of higher technical training.

Of especial significance is the system of industrial education being developed in the Soviet Union. The gigantic effort of the U. S. S. R. through a planned economy to transform Russia within relatively few years from a nation of peasant agriculture and household industry to one that is highly industrialized includes a vast scheme of cultural and technical development to match a vast scheme of increase in productive equipment. There has been created a system which includes primary and secondary schools for the masses, in which emphasis is on promotion of understanding of the national economy, schools for the training of engineers and other technicians and for every new factory a school for the training of its operatives, adult as well as young. By compulsion of circumstances the entire scheme has a practical and utilitarian emphasis, for the immediate objective is, first, to train the citizens in understanding and support of Soviet purposes and organization and, second, to train workers capable of operating industrial equipment as rapidly as the factories are constructed. Therefore instead of the youth being withdrawn from community life for an extended period of education, training is integrated with livelihood and political activities. In 1931 in addition to 20,000,000 boys and girls in elementary and middle schools there was the following enrolment in schools established for the training of cadres for the national economic plan: higher industrial and agricultural, 255,000; industrial and agricultural technical, 444,000; factory training, 1,198,000; workers' faculties, 232,000.

Late in the nineteenth century educators in the United States became interested in manual training and by 1900 it was winning status in American schools. Contrary to the originators' concept of it as an element of cultural training, American educators then regarded manual training as a means of industrial education which would answer the criticism, beginning to come from industry, that the schools were not training youth adequately for its needs. This first mistaken appraisal of manual training served at least to direct the attention of educators toward the problem of training for industry. The new interest was strengthened by the theory of education, first prominently expressed in John Dewey's *The School and Society* (New York 1899), that education is basically a means of adjustment to life's activities. The influence, however, which welded these tendencies into a

conscious movement was the acquisition by the United States of its first colonial possessions after the war with Spain. It was naively assumed by many that the United States was destined promptly to make a "commercial invasion of Europe" and to become great in foreign trade and that the intense international competition involved would have to be supported by an increasing industrial efficiency. Since Germany within thirty years had become strong in international trade partly through her system of industrial education, it was now incumbent on the United States to develop a similar instrument. Consequently attention was turned from manual training as an instrument of vocational education, although it was given higher status as a factor in cultural education and in prevocational discovery of aptitudes, to something more like the German system.

In the United States, however, there was no central government with the power to establish a "system," and the development of industrial education could come about only through independent state action. The movement was begun in Massachusetts by two commissions on industrial education consisting of business men and educators appointed by the governors in 1905 and in 1906. It spread to national proportions with the organization of the National Society for the Promotion of Industrial Education in 1906, a symposium on industrial education held by the Department of Superintendence of the National Education Association in 1908 and occasional national vocational guidance conferences. By 1910 more than a dozen states had passed legislation initiating the beginnings of local systems of industrial education. Under the joint influences of the National Society for the Promotion of Industrial Education, the National Education Association, the National Association of Manufacturers and the American Federation of Labor this movement finally culminated in the passage of the Smith-Hughes Act (1917), whereby the national government established a Federal Board for Vocational Education to supervise federal contributions in support of industrial education in the several states. This stimulated state legislation relating to industrial education and at the same time established a force promoting unification in organization and procedure throughout the country.

The Smith-Hughes Act leaves the organization, administration and development of industrial education to the several states but is a powerful force in influencing their conduct.

Under this influence the total enrolment in all vocational schools and courses increased from about 25,000 in 1917 to about 1,125,000 in 1931. Registration in these schools was distributed in 1931 as follows: agricultural, 237,361; trade and industrial, 602,356; home economics, 285,519. Of those enrolled in trade and industrial classes the distribution in 1931 was: evening, 168,822; part time trade, 47,471; general continuation, 295,042; all day trade, 80,541. The total expenditures, federal and state, for vocational education increased from \$3,039,000 in 1918 to \$32,139,000 in 1931, of which the federal contribution increased from \$832,000 to \$7,978,000 and the state and local contribution from \$2,206,000 to \$24,160,000. The state and local contributions are required by the act to be at least equal to the federal contributions, but the former have increased so that they represent \$3.03 for every dollar of federal money. The act has helped also to raise the quality of vocational education. It provides that states accepting federal funds must have a supervisory state board, the instruction given shall be suitable to persons fourteen years of age and over, it shall be of less than college grade, the funds shall be used to train individuals who either are employed or are preparing for employment, and the state and local contributions of dollar for dollar shall be used for the same purposes as the federal contribution. In cooperation with state boards the Federal Board has been able to effect a progressive improvement in the organization of curricula and the training of teachers. A marked improvement in the quality of teaching has been achieved by more careful selection and by reorganization of the system of training teachers. While numerous colleges and normal schools still provide a basic training, the principal training of vocational teachers is now on the job. Each of the fifty state and territorial units has its director with a staff of state supervisors, local supervisors and teacher trainers. Training is therefore continuous after employment and is brought to the teacher at the place and in terms of his local educational problems.

The present system of publicly administered industrial education in the United States is the outcome of a fifteen-year intensive campaign of pressure on public authorities; but even before 1900 private trade schools were in existence, such as the New York Trade School established in 1881. By 1910 there were a dozen such schools so endowed as to be free from commercial considerations and able to offer excellent training.

In addition to these there exist today perhaps two hundred privately organized trade schools, conducted as commercial enterprises, which arose originally in response to a real need caused by the breakdown in the apprenticeship system. Most such schools today are relatively inferior as to equipment, staff and training capacity. There are also hundreds of small trade preparatory schools designed to give preparatory training as a basis for later specialization and several notable technical high schools to train students for positions above the level of ordinary skilled labor.

Some of the larger industrial enterprises in the United States have organized what are known as corporation apprenticeship or co-operative schools for their employees. The pioneer schools of this class were those of Hoe and Company, established in 1872, the Westinghouse Machine Company in 1888, the Baldwin Locomotive Works in 1901, the General Electric Company in 1901 and the International Harvester Company in 1903. After 1905 this movement grew rapidly. Among more recently organized large schools of this type are those of the Ford Motor Company and the General Motors Corporation. The National Association of Corporation Schools organized in 1913 had before it was merged with the American Management Association in 1922 nearly 150 members. Distinct from these highly organized corporation schools with their comprehensive curricula are vestibule schools, a simple but effective device forced upon industry during the World War to meet the problem of labor shortage by rapid training of the new inexperienced employees with which labor forces were then diluted. There are also continuation schools conducted by the Young Men's Christian Association and the Young Women's Christian Association which render a genuine service. The schools not publicly administered fail, however, to reach the masses of people because they are limited in number and are in some cases too costly. In so far as there may be said to be a system of industrial education in the United States, the state part time or cooperative vocational schools administered under the Smith-Hughes Act constitute that system.

The organization of vocational education under that act, however, is being subjected to a wholesome critical scrutiny by educators and the general public. This scrutiny has been focused especially on two questions: whether the influence of the federal government on the educational

policies and administration of the states is beneficial, and whether the nature of the instruction meets the problem of vocational adjustment. The former question is on the whole a continuation of the century long debate of centralization versus decentralization in government and, while the final answer has not been discovered, the burden of proof remains on those advocating state individualism.

Whether the nature of the instruction in industrial education meets the problem of adjustment is questionable. The technical characteristics of industry have been changing so rapidly that administrators of educational affairs have not been able adequately to analyze and follow them. The basis of the American democratic school system was for many years the leisure class ideal of education. Every youth was to be trained as though he were destined for the university. Later educators responded to the obvious need of educational opportunity for the increasing number who were leaving schools at an early age and to industry's increasing demand for skilled workers. Since, however, there is no organized apprenticeship system in the United States, the tendency in industrial education has been to assume that trades may be taught in the schools. The growing opinion is that instruction in the details of trade technique is a responsibility which industry must assume and for which industry must organize and that the schools must concentrate on discovery and development of aptitudes and attitudes, on a broad training in the arts and sciences underlying trade techniques and on industrial economics and citizenship. Industrial education with such an objective, supplemented by factory conducted training in the details of technique, would in large measure answer the demand for more adequately trained foremen, which is a critical problem of American management.

Training for occupational flexibility and adjustment and for industrial citizenship must play an important part in the solution of problems now confronting advanced industrial societies and occupy an important place in the industrial organization of the future, whatever its nature. If an industrial society remains predominantly individualistic and laissez faire it must safeguard itself by increasing the fitness of constituent individuals not only for existing occupational demands but also for adjustment to technological change, in order to remove the hazard of economic insecurity which is now a threatening problem of individualistic capitalism. If such a

society undertakes to insure its members against that hazard through some system of unemployment compensation, its ability to carry such a burden from the actuarial point of view will depend largely on its success in reducing the risks insured. This will likewise require among other things improvement of the fitness of individuals for technological demands and a flexibility in adaptation to new opportunities as familiar ones disappear with technological progress. It is significant that practically every proposed scheme of unemployment insurance makes unemployment exchanges a vital part of the scheme. Such exchanges will be able to function effectively only in terms of occupational specifications which are definite and of personality specifications which are equally definite and couched in terms of capacities.

If, on the other hand, as is likely to be the case, an industrial society elects to modify the individualistic characteristics of its organization and to establish some degree of regularizing social direction of its industry, it will discover that the planning involved must be in terms of human capacities as well as of capital equipment available for the technical operations which will satisfy the ascertained demands; that these human capacities must be definite, technical and flexible; and that the creation and maintenance of the proper proportions of various human capacities and technical skills must constitute a part of the planning. It should be observed that the industrial education of the U. S. S. R. noted above is an essential part of its efforts to build a planned industrial society; and it is obvious that if and when that particular form of industrial society becomes mature and is confronted by the problem of satisfying the variable demand of a higher standard of living for a large proportion of caprice goods, its capacity for precise applications of labor skill will be more critical and will depend on a more highly developed system of industrial education. In any society which has organized a substantial social direction of industry training of an understanding, cooperative body of citizens is especially necessary.

INDUSTRIAL HAZARDS may be defined as those dangers to life, limb and health which arise out of the processes of production. Occupational hazards are not peculiar to the modern era. The environment, man's effort to conquer it and the tools he uses in this effort contain the possibility of injury to the human body and have always represented an element of hazard. Hunting, fishing, forestry, transportation by land or water and the tilling of land were sources of accidents wherever and whenever they were practised. Certain occupational diseases were recognized by philosophers and physicians of ancient times, although the widespread use of slaves contributed to a general indifference to the problem. Thus Pliny comments on the "diseases of slaves" and other writers remarked on occupational hazards to miners of lead and quicksilver, potters, textile workers, burden carriers, gardeners, smiths, tailors and workers in flint, sulphur and zinc.

But in neither the domestic nor the handicraft stages of production was the health of the worker believed to be the concern of anyone but himself. Even the guilds offered little health protection to the workers in the face of overcrowded, unsanitary conditions in towns and the hazards of the metallic and textile trades which must have been prevalent in the Middle Ages. It was not until the sixteenth century that physicians began to inquire even in the most casual fashion into industrial health problems. The entire subject was reviewed in 1700 by an Italian doctor,

Bernadino Ramazzini, in the famous *De morbis artificum diatriba* (Modena, 2nd ed. Utrecht 1703; English translation, London 1705). This book was for the times a masterly treatise covering a multitude of trades and establishing two principles of industrial hygiene—that of prevention and that of investigation by doctors of the occupation of every patient under their care—which are valid, if not generally observed, today. The transactions of the Royal Society of London also record some interest in working conditions in mines and manufactures in the late mediaeval period. Unfortunately, however, no reliable data on the increase or decrease of occupational injuries at various stages of history can be compiled from these scanty data. Those covering the brief period of the latter part of the modern industrial era would seem to show an alarming increase of certain hazards; but, on the other hand, there is little doubt that the occupational hazards of earlier ages have been very much underestimated.

Perhaps all history of civilization might be described as a process of making life safer as well as more satisfying. The hazards of weather were eliminated through improved housing; the hazards of wild animals through their destruction; the hazards of pathogenic germs through progress in medicine and hygiene; the hazards of famine through better methods of agriculture and improved transportation. Simultaneously another process was going on, tending in a diametrically opposed direction: new hazards were being created through increasing use of new and complicated tools and processes and through increase and congestion of population. These two opposite tendencies have not always kept pace with each other. The increase in recent years of both the hazards and the attention to them is not, however, entirely due to introduction of new processes; an equally important factor has been the rapid extension of the wage system. The two factors are closely related, although it is possible to visualize a wage system of production without the continuous introduction of complicated and dangerous processes; and it is equally possible to visualize the progress of these processes without an increase in the proportion of wage earners.

While the physical aspects of industrial hazard—the damage to life, health or limb—or even the economic aspects—the destruction of earning capacity, the enforced idleness, the cost of reestablishment of health—may be the same whether the victim be an employee or an inde-

pendent worker, yet in its social aspects the situation is greatly affected by the existence of the wage contract. This difference in attitude is due partly to a sense of group justice based upon the feeling that the hazard might have been eliminated through the action of a third party, who therefore must bear the responsibility; but it is also based in part on a new economic situation which has arisen out of the wage contract. As the able bodied employee must look to his employer, or rather his employment, for an opportunity of earning a living, so the disabled employee and his dependents may have to depend on the employer and industry for relief and restitution. In other words, industrial hazards have become one aspect of the general relationship between capital and labor.

The industrial worker may be menaced by any or all of the three types of industrial hazard: disease, poison or accident. The sickness insurance legislation of Europe has done much to lay bare the cases of poison or disease in industry, but the records of these hazards are inadequate and frequently inaccurate in the United States. The sources of information are chiefly local studies by state departments of labor, trade unions, insurance companies or private investigators or the intermittent reports of hospitals, company physicians and the workers themselves. As only ten of the compensation laws in the United States cover industrial diseases, the cases reported under the laws probably represent but a small fraction of the total actual number. Except for injuries resulting fatally, statistics on the frequency of accidental injuries are also very inadequate. In 1928 there were recorded in the registration area 90,712 deaths due to external accidental causes, exclusive of 15,566 suicides and 10,050 homicides. Adjusted to the entire population of the United States this would give a total of some 95,000 accidental deaths. The Rubinow Standard Accident Table indicates that approximately one of every hundred industrial accidents results fatally. If the same proportion may be assumed for all injuries whether industrial or not, the total of accidental injuries would approximate 9,500,000 a year. On the whole, the total number of fatalities and perhaps of all accidents may be roughly divided into three equal parts: those due to transportation, all other non-industrial accidents and those arising from industrial activity. Hence in absolute figures there are probably over 30,000 fatalities and 3,000,000 non-fatal injuries in industry annually in the United States.

Appraisals of the probable hazard presented by any industrial situation are now made, but the degree of accuracy of such appraisals must always remain problematic. A scientific measure of the hazard is possible only on the basis of past experience of damage caused by the particular machine or situation. Such statistical measures are lacking in the case of poisons and diseases for several reasons: first, such illness is much more likely than an accident to affect every worker in a certain process and hence its incidence should be measured by severity rather than frequency; second, industrial poisoning and disease are generally chronic rather than acute and therefore less open to discovery; third, the specific cause of an industrial disease is sometimes hard to identify, particularly when a worker is exposed to several possible sources of illness. Moreover there are relatively few cases where sickness insurance or compensation is provided for sufferers from industrial maladies, and a doctor is not compelled to record a disease as industrial or otherwise except under these systems. As a result agitation for reform has usually been the outcome of sensational disclosures rather than scientific measurement of hazard; for example, the disfigurement following phosphorus poisoning was such effective propaganda that the use of phosphorus in matches was one of the first dangerous processes to which attention was given, although there are other industrial maladies equally widespread and serious. If compensation or insurance is paid the degree of danger in an occupation may be revealed; this was the case in France, where the manufacture of matches was a state monopoly and the compensation which the government was paying to workers in the trade was so heavy that the substitution of the non-poisonous sesquisulphide became imperative. But until adequate information on the occupation of patients is required by hospitals and doctors and by death certificate laws or until the compensation laws cover all forms of industrial ill health, no statistical measure of the hazard in poisonous or disease bearing trades will be satisfactory.

In practise even the statistical method is subject to very definite limitations. While statistics of industrial accidents have been compiled independently of any scheme of compensation, experience has demonstrated that only through a compensation system and the stimulus it gives for complete reporting are adequate statistics possible. But since no workmen's compensation scheme includes all industrial activity, it follows

that no accident statistics are at present complete. In this respect European countries are considerably ahead of the United States. Industrial diseases and poisons are covered either in sickness insurance or, as in Great Britain, under the compensation law; in the United States all occupational diseases are covered in only five of the forty-four compensation laws—those of California, North Dakota, Wisconsin, Massachusetts and Connecticut—and under three federal laws applying to harbor workers and government employees. In five states industrial diseases are covered by means of the specific schedule method, i.e. by listing certain compensable diseases: Minnesota, Illinois, Ohio, New York and New Jersey. Accident statistics also are more complete in Europe than in the United States. The laws cover the entire country and are subject only to rare changes, whereas the bewildering variety of compensation acts in the United States and their frequent changes have hitherto stood in the way of uniform and dependable accident statistics. Efforts to introduce uniformity in accident statistics have been made by such bodies as the American Association for Labor Legislation, the International Association of Industrial Accident Boards and Commissions and the Association of Governmental Officials in Industry of the United States and Canada. Frequently the United States Board of Labor Statistics has supported such movements, but no complete compilation of accident statistics has ever been attempted by a government agency in the United States. Comprehensive plans of uniform statistics have been published, but as yet the degree of uniformity achieved has been slight. Somewhat greater uniformity has been achieved in the reporting by casualty insurance companies and some of the more important industrial states, particularly New York, Pennsylvania, Wisconsin and California, have elaborated satisfactory systems of industrial accident statistics. The International Labour Office is attempting to publish accident statistics for the principal countries at intervals of six months, but because of differences in methods of compilation these data are not comparable.

Another difficulty is the exact definition of an industrial disease or accident. The problem of diagnosis mentioned above, where the worker has been exposed to more than one source of poison or disease, arises frequently in the case of such important industries as the coal tar dye and chemical trades, printing, rubber manufacture and painting. In the case of certain infec-

tions, such as tuberculosis, it is often difficult to determine whether the disease was contracted at work or elsewhere. Finally, the limitations of medical knowledge itself still retard complete and accurate definition of industrial diseases. With respect to accidents changes in the type of injury reported may occur from time to time, so that as the system of reporting is made more thorough more and more minor accidents are reported and time comparisons become unreliable. A study of comparative hazards of specific industries offers greater possibility of accuracy, but even there the accident as a unit may prove unsatisfactory because of the vast difference in suffering and cost caused by accidents of different severity. In recognition of these differences the concept of accident severity rather than accident frequency has grown up as an additional unit of measurement, the unit being rather arbitrarily based on loss of time per 1000 days of full employment rather than the number of accidental injuries per number of employees.

The most complicated and at the same time the most important aspect of such statistics is the standardization of causes and contributing factors. Since a perfect description of any accident, poison or disease may disclose several "causes," the technical complications of such statistical analysis are obviously very great. Nevertheless, if the volume of statistics analyzed is sufficiently large, it is frequently possible to discover a high enough correlation between frequency of accident or disease and certain conditions to indicate a causal connection. Thus a certain periodicity of accidents has been discovered. Fluctuations according to the season of the year may of course be due primarily to corresponding fluctuations in the volume of employment. The hour of the day has been found to be a factor. The influence of increased fatigue has been accepted as a possible explanation, and there are indications that even without the question of fatigue the gradual increase in intensity of effort through certain hours of the day or through the week may be a contributing factor. Factors influencing the amount of poisoning are hot and humid air, long hours, malnutrition, alcoholism in the case of some poisons, constitutional defects such as anaemia, and personal susceptibility. Industrial diseases arise in part from such secondary causes as imperfect ventilation and inadequacy of washing facilities, fatigue, strain, the habits and home living conditions of the workers and insanitary or unhealthful methods of work.

In general, comparative study seems to indicate a lower degree of industrial hazard for agricultural countries and countries with simple industrial activity, even though it is possible that this difference may be overemphasized by a lower degree of completeness in reporting. A study by Dr. Louis Dublin revealed that the average expectancy of life of industrial workers was eight years less than that of those engaged in agricultural, commercial and professional occupations. Of these eight years one year could be attributed to mortality from accidents, and from eighteen months to two years to death from tuberculosis. Degenerative diseases as causes of death were from two to three times as high in the industrial group, and pneumonia was twice as frequent. Even among industrial states the hazard varies greatly, depending on the character of the industry. Thus the average industrial hazard, measured either by the total population or by the total number of persons employed in industry, is higher in Pennsylvania with its mining and heavy metal industries than in New York with its predominance of the less hazardous needle trades, publishing houses and the like.

The degree of industrial hazard varies for different elements in the population. Women are subjected to a lower hazard than men, partly because there is a smaller percentage of them in industrial employment but also because within industry they are usually concentrated in occupations of lower hazard. Men lead also in severity of disablements and show a higher mortality from pneumonia, but women lose twice the time of men from common colds, influenza and tonsillitis. Oliver believes that women are more susceptible than men to lead poisoning, one of the most important types of industrial disease in the United States. Children also show a lower industrial hazard for the same reasons as women, but once exposed they are more susceptible to diseases and poisons; and youth is one of the chief personal factors in the occurrence of accidents—about 75 percent of accidents injure workers under twenty-five years of age. Whether women and children, if subjected to the same objective exposure, would show a greater or less general susceptibility remains uncertain; but legislative restriction of employment of women and children is largely justified by the danger to themselves and others of permitting them to handle disease bearing or poisonous materials or complicated pieces of machinery.

A higher susceptibility of older age groups to industrial accidents is often taken for granted

because of weakened senses and reduced power of muscular coordination, but statistical evidence as yet is meager. The general intelligence of the worker, his educational level, his skill and familiarity with mechanical appliances, strongly influence susceptibility to industrial injury. Reports compiled by accident boards show in some cases 81 percent of the accidents occurring on the first day of employment and 96 percent in the first week. Perhaps over and above all these general factors is that of specific training in hygiene and safety with particular reference to certain hazards, which bears the same relation to industrial hazards that health education bears to the general level of sickness.

While all these elements are important, statistically the nature of the industry remains the most influential factor in determining the degree of hazard. The difference in the hazards of various occupations is so great as to justify a sharp line of division between dangerous and safe employment. At one extreme are work at sea, mining, heavy metal industry and construction, particularly if at a great height or involving caisson work, tunneling or the use of explosives, and certain chemical industries. At the other extreme are the manufacture of clothing and clerical work. Between these two extremes a great variety of hazard rates exist, largely based on the degree of utilization of machinery or chemical processes; but no employment may be assumed to be entirely free of industrial hazard, since a substantial proportion of accidents and other hazards is due to the ordinary frailties of human behavior and is not related to mechanical appliances at all.

The types and sources of industrial poisons and diseases are so numerous and so difficult to isolate that only the more important can be mentioned here. The principal occupational diseases vary in different countries: poisoning is most common in Switzerland and Germany, miner's nystagmus is prevalent in England, silicosis in South Africa and Australia, hookworm disease in warm climates and dermatitis and lead poisoning in the United States. To some extent differences between individual establishments in the same industry may be purely fortuitous or unexplainable; but they may also express the difference in methods of organization and administration of the process of production as a whole, particularly along the lines of industrial hygiene and safety. Thus lead poisoning in Europe arises now chiefly in the manufacture of cheap kitchen ware, dyeing of cotton and wool,

making of files and polishing of diamonds. Preventive measures have controlled it in Europe in the very trades where it is most common in the United States: most important of these measures are the manufacture of white lead by a dry instead of a wet process, the use of non-fritted white lead in pottery glazing and in printing establishments. The lead hazard is not easily controlled in rapidly growing and profitable trades; for example, in the enameling of sanitary iron ware in the United States. Through legislative and preventive measures there has been an enormous improvement in the lead using trades in recent years; but white lead is still widely used in the United States by painters and potters and red lead is employed in the manufacture of storage batteries, printing inks, leaded glass, linoleum and glazing tiles and terra cotta. The felt hat trade is also unhealthful in all countries, because of the large quantities of fine fur flying about in the air and the use of mercury in the process of manufacture. The protection of workers is most complete in Europe, although individual factories are frequently superior in the United States. The trade is especially hazardous in France, Belgium and Soviet Russia. In the last named country preventive measures were introduced in 1924 but, since the felt hat trade is almost entirely a home industry, knowledge of these measures has not yet effectively permeated to the peasant workers. Benzene poisoning is a prominent hazard in the American canning and rubber industries and phosphorus still menaces the brass founders, fertilizer and insecticide makers, bronze workers and match-makers as well as the phosphorus preparers themselves. An investigation made in England in 1928-29 would seem to indicate that one out of four workers in the preparation of asbestos for over five years is affected by the lung disease known as asbestosis. The harmful effects of silica dust have been established by the fact that zinc and lead miners show a mortality from tuberculosis eight times as high as among "standard" lives. In general it is believed that inorganic dusts encourage tuberculosis, although the reason for this is not known; hence workers in dust creating trades are subjected to a considerable hazard.

Obviously, industrial hazards represent a social loss of considerable magnitude measured in pain, loss of life, loss of earning capacity, cost of restoration and disturbance of economic efficiency. It is impossible to sum up the emotional loss to families of victims of industrial fatalities

or the total amount of pain and distress caused by those suffering industrial injuries, particularly when the result is permanent disability or disfigurement. A somewhat greater approximation to economic costs is possible. To the injured wage earner or his family it is a question of loss of wages and cost of care. From the point of view of the employer the measure is the cost of compensation insurance. From the point of view of society at large the problem is primarily that of loss of productive capacity. Estimates based on these various points of view are likely to vary considerably. The most complete data available deal with the total amount of compensation paid to injured workmen. On a basis of careful computation this has been estimated by the United States Bureau of Labor Statistics to approximate \$240,000,000 a year; but, as already stated, compensation does not by any means cover all industrial activity. Moreover the relation between compensation and the actual loss sustained by the worker varies not only under different acts but under the same act according to the nature of the accident, the wage earning capacity and so on. It has been estimated that on the whole compensation legislation does not cover more than one fifth or one sixth of the loss sustained by the injured workman; thus the total social cost of industrial hazards in losses of earning capacity and expenses incurred may be roughly estimated at \$1,000,000,000 or \$1,500,000,000 a year. Primarily, wage earners carry this burden. Employers share in the cost to a limited extent only, either through decisions under the liability law or through the cost of compensation insurance. It is believed by some economists that a part if not all of this latter cost is included in the price of the product and is thus shifted to the consumer. In so far as compensation does not meet the entire need created the public is called upon to meet it through public or private charity.

Thus industrial hazards represent to society a dead loss of considerable magnitude. The social problem presented is that of their elimination or at least their reduction to the lowest possible minimum. This involves study of the dimensions of the problem, of causative factors, of methods of elimination of hazard and the best method of applying such methods as have been discovered and, finally, of the best method of spreading out the social cost so that it does the least harm to any one group or society at large. The control of industrial hazards therefore requires various methods of approach: the statis-

tical, the technical, the medical, the economic and the social.

The first technical problem created by the introduction of power driven machinery and mechanical appliances is that of making the machine safe. If the superior value of life and health over economic advantage were universally recognized, the task would be comparatively simple. In fact, however, the conflict between the interests of the employer and employee often creates considerable difficulty, and in such cases it is only through legislative power that it is possible to eliminate the process and thus the hazard. The method of direct prohibition of a process has been more successful in relation to chemical processes than to mechanical devices. In England the use of non-fritted white lead in pottery glazing was abolished by law after years of effort for reform; in the United States the elimination of phosphorus in match manufacture was effected by federal taxation, which made the dangerous process as expensive as the non-poisonous one. Usually the elimination of poisonous or dangerous processes is possible only when other equally effective, although perhaps more expensive, methods are available.

Within recent years the problem of reduction of hazards has become sufficiently important to command both theoretical and practical attention in the form of industrial hygiene and safety engineering. At first these fields dealt primarily with the guarding of machines, control of dust, the use of sanitary masks, antiseptics, substitute materials and preventive devices. Only gradually did factory management learn that there are many other factors in the organization of an establishment which contribute to industrial hazards. Such problems as spacing of machines, better lighting and control of the human factors of production command a constantly growing attention from safety engineers. Safety may also require the total elimination of certain individuals or groups who are considered substandard from the point of view of coordination of power, judgment or susceptibility.

The degree of industrial hazard is measurable not only by what happens during the occurrence of the accident or illness but also by the degree of attention and care given to the injured person. Infections of minor injuries have been shown to lead frequently to more serious developments. A system of immediate reporting, adequate first aid and continued medical attention becomes one of the chief functions of the safety movement and constitutes now an important

part of factory administration. The necessity for the education of doctors in the symptoms and treatment of industrial diseases and poisons is still pressing.

Since prevention depends upon control of the entire process of production, the main responsibility necessarily lies with management, but labor also carries a share of responsibility. In practise, however, the necessary cooperation is not always found, because the elimination of the hazard represents a definite cost, while the hazard itself may appear only as an uncertain and hypothetical cost. Cooperation sometimes fails because of lack of understanding on either side or perhaps because of a strained relationship between management and workers arising out of other aspects of the labor problem. Frequently workers resent safety regulations simply because they are imposed from above. These difficulties have occasionally been met by the intelligent cooperation of management and labor organizations, and agreements as to safety conditions sometimes constitute part of the process of collective bargaining. The poisonous trades as a whole are not well organized in the United States and partly for that reason the workers have not been active in the hygiene movement. The unions which exist are not perhaps sufficiently concerned, with the problems of disease in particular. For example, the International Typographical Union has never made rules preventing the exposure of young boys to lead dust, although such regulations have been considered necessary in all European countries. The best known movement for general health protection is that of the Joint Board of Sanitary Control of the International Ladies' Garment Workers' Union, which was set up in 1910 and whose duties comprise sanitary, medical and safety education and inspection.

In the vast majority of cases, however, particularly where labor is not organized, it becomes the function of the state to introduce regulation by exercise of compulsion upon both employer and employee. Provisions for safety were among the earliest objects of factory legislation and inspection, arising largely in response to the introduction of dangerous machinery. Gradually these provisions extended into the fields of sanitation, health and even increased comfort for the labor force during the process of production. Factory legislation now seeks to safeguard the machine, to improve general standards of factory construction, to exclude certain hazards or exclude certain groups from certain hazards, to

regulate hours and in some cases to demand fire drills or first aid systems. Specific conditions are subject to infinite variety in various branches of industry, and factory legislation has become one of the most complicated branches of all labor legislation.

Since modern industry is unable to eliminate industrial hazards completely, the question of cost remains an important one. The complacent theory of classical economics that wages will be adjusted through a process of free competition so as to include additional compensation for the risk involved has never received statistical confirmation and may be disposed of as a rather obvious rationalization of resistance on the part of employers toward assuming the cost for the injury. The voluminous legislation of the last century, dealing with employers' liability, may serve as an indication of a shifting from the point of view of purely personal responsibility to some sort of social policy in dealing with the consequence of industrial injuries.

The effects of compensation laws have been debated ever since their inception: their opponents claimed that they would lead to carelessness and malingering on the part of employees, while their supporters argued that when the financial responsibility for injury was placed on the employer and on industry preventive measures would be increased in order to avoid financial losses. The experience of the past twenty years is not so conclusive as an ideally uniform and complete system of statistics might make it. There has certainly not been any increase of carelessness or malingering on the part of employees as was feared, for even the most liberal compensation acts do not make full restitution for losses sustained and it is but seldom that the advantages of compensation exceed the disadvantages of sustaining an industrial injury. In many of the less hazardous industries the cost of workmen's compensation has not proved a sufficiently great factor to modify the system of productive organization. Undoubtedly certain establishments or corporations have shown striking results, sometimes because of an effective safety organization but more often through a fundamental change in industrial processes. The experience of the United States Steel Corporation is frequently cited in this connection. But taking industrial accidents as a whole, many communities, such as, for instance, the state of New York, continue to show an increase in both frequency and severity. Only too often is temporary reduction in the total number of accidents

or cases of disease used as evidence of increased safety when the reduction is due to a shrinkage in industrial employment. It is very likely that not only the number of accidents and diseases but also their rate increases in times of prosperity because the very tempo of industry, the congestion of establishment, the number of hours worked and the frequency of overtime and night work, all tending to influence disease and accident, vary according to the amount of general economic activity.

One of the most important influences for prevention of industrial hazards under workmen's compensation laws is the insurance carrier. It is conceivable that an employer may disregard the increased cost of compensation because of hopes of greater profits under greater industrial stress and with fewer safety measures, but the insurance carrier has a direct interest in the reduction of industrial accidents. The assertion of a recent writer that "the extension of modern accident prevention methods is due largely or almost exclusively to casualty insurance companies" may be exaggerated; but all carriers, both private and state, have played an important part by inspection, advice, premium adjustment and occasional rejection of unsatisfactory risks.

It is recognized by modern psychologists that in so far as carelessness and failure to utilize available safety measures result from definite thought and behavior patterns safety education must begin much earlier than active participation in industry. The problem of proper education to avoid industrial hazards becomes a part of the very much larger problem of adjustment of the entire educational system to the needs of processes of production. Failure of such adjustment is marked in the United States; in fact, an examination of the American system of public education might result in the impression that it is a nation of traders rather than producers.

It must be recognized that there are indications of a continual increase of industrial hazards. New types of machinery are steadily being introduced; new chemical preparations will continue to be tested out; new dangers will therefore develop. On the other hand, in so far as individual hours of work decrease, in so far as mechanical power is substituted for human effort so that the sum total of contact of man and machine is reduced, industrial evolution may reduce rather than increase industrial hazards. It is less important to dream of the total elimination of industrial hazards than to give serious thought to conquest of each hazard as it develops

and to reduction of social damage caused by industrial ill health.

That there is frequently a connection between the profit motive and private ownership on one side and the hazardous nature of industrial processes on the other cannot be gainsaid. Under existing economic relationships dangerous processes are sometimes continued because they are profitable; methods of prevention or safety are neglected because they are costly. But the careful study of industrial accidents and disease cannot lead to the conclusion that the profit motive is the only or even the most important factor. In Soviet Russia there has not only been an increase of accidents since the pre-war period but there was also a marked increase in the three principal industries, metals, mining and textiles, from 1925 to 1927. The causes are the diversity and worn condition of the equipment, insufficient mechanization, especially for conveying and lifting goods, the high labor turnover, the lack of skill and the speeding up process. These factors have apparently outweighed up to the present time the effect of thorough inspection service, compensation and hundreds of prohibitions of dangerous processes by state legislation. Hence the only practical application of the socialist theory which can be studied from actual experience offers as yet little hope of a total elimination or even a rapid reduction of industrial hazards. The imperfections of the human machine may remain a more important factor in the responsibility for industrial hazards than the imperfections of the economic machine.

INDUSTRIAL HYGIENE

HISTORY AND DESCRIPTION. Although the hygiene of industry in its broadest sense deals with all the conditions under which work is carried on and under which the worker lives, in modern times its main concern is with the various harmful agents to which the worker is exposed as a result of industrial processes, such as fumes, dusts and high temperatures.

It is impossible to state with accuracy when industrial hygiene first became an object of serious study. As far back as the period of Babylonian civilization occupational diseases were known, for tablets found refer to lead poisoning and pulmonary diseases of the workers. Greek and Roman physicians were likewise acquainted with occupational diseases and there is evidence that certain preventive measures were adopted; for example, Pliny's statement that masks were used by workers in vermilion to protect themselves from metallic dust. Writers from 5000 B.C., when copper is said to have been first mined in Egypt, down to the Christian era allude to the terrible sufferings and physical deformities of women and children employed in mines and quarries. But, with the exception of an edict of the Rota in 643 A.D. making it compulsory for employers to compensate masons for injuries received when repairing houses, there is little evidence of common recognition of occupational

risks and possibilities of their elimination or compensation.

In the Middle Ages medical men were familiar with the maladies incidental to mining and smelting, and a pamphlet on poisonous fumes and vapors published in the fifteenth century suggests preventive measures. But the greatest impetus to the study of industrial hygiene was given by Ramazzini, an Italian born in 1633, who practised medicine in his native town and subsequently became professor of medicine in the University of Parma. His careful studies of all forms of occupational disease and his recommendations for their prevention make him one of the greatest authorities on the subject. Other publications, often based on his work, appeared in the eighteenth century; among these the best known are that of Hecquet in 1740, that on the maladies of craftsmen by Skragge of Uppsala in 1764, the studies of chimney sweep's cancer by Percival Pott in England in 1775, the *Annalen für Staatsarzneikunde* in Germany in 1782 and the studies of the dermatologist Willan in 1798 on the skin diseases of bakers, shoemakers and metal workers. Group action for the prevention or cure of industrial diseases seems to have been organized only in Italy, where a clinic was opened at Legnano in 1784 for sufferers from pellagra and industrial workers attacked by tuberculosis.

The rise of the modern factory system with its overcrowding, intensified productive effort and dangerous machinery emphasized the necessity for industrial hygiene measures. In some industrial centers in 1833 the average age of the working class group was found to be only half that of the upper classes, and the death rates of the two groups also showed a striking difference. The factory legislation which began in England in the early nineteenth century, somewhat later in France and toward the end of the century in Germany and the United States represents the first attempt to ameliorate the conditions leading to ill health and low physical resistance of factory workers. Under the laissez faire traditions of the time it was difficult to do more than provide protection for particularly susceptible groups, i.e. women and children. The regulation of hours, prohibition of night work and work in certain dangerous and unhealthful trades and other special legislation for these two classes of workers represent the only outstanding action in behalf of the health of the worker in the nineteenth century. Contributions to the study of general occupational risks, however, began to

appear with the rise of preventive medicine in England and France in the first half of the century, in the United States in the 1880's and 1890's and in Germany somewhat later. But the extension of health protection to all workers in the form of heating, lighting, ventilation and sanitation requirements as well as investigation and regulation of dangerous trades was slow to develop. It was not until the appearance of the industrial engineer in the twentieth century that the scattered regulations on these subjects were standardized.

Industrial health hazards arising out of the nature of the process or the substances used as opposed to those created by general working conditions may be divided into four groups: dusts, poisons, work in hot or humid temperatures or under abnormal air pressure, and incidental disease furthered by certain working conditions.

Before the introduction of the double shaft system of ventilation coal miners succumbed in large numbers to the lung disease known as coal miner's phthisis, or anthracosis. Today owing to improved ventilation of the mines this type of miner's phthisis is seldom seen, although the miner is still subject to tuberculous infection if small particles of stone from the coal are lodged in the lungs. Additional hazards to which the miner is subject are poisoning from carbon monoxide and methane gas; painful physical disabilities affecting the hands and elbow and knee joints; and nystagmus, a nervous disorder affecting the gait and vision which is particularly prevalent in England, France and Belgium. Other dusty occupations are the mining of gold, tin and lead; the shaping of grinding stones for milling purposes and for the pulverization of flints; the manufacture of pottery and china; the dry grinding of steel by emery wheels; the sand blasting of metal castings and the face of stone buildings; and the weaving of asbestos into clothlike material. Of organic dusty trades the most important are woolen and cotton manufacture, where opening of bales of raw material and spinning and weaving are usually attended by dust.

Lead causes more ill health than any of the other poisonous fumes and dusts. This results from the toxic properties of the metal and the fact that apart from the heavy industries there is no other metal so widely used. So long as a lead miner is working in ore known as galena, or sulphide of lead, and not cerussite, or carbonate of lead, he incurs no risk of lead poisoning but he does run the risk of pulmonary disease. The

harmfulness of lead compounds used in industry depends primarily upon their solubility in the juices of the body and the receptiveness of the person brought into contact with them. Among the industries in which lead poisoning is very prevalent are the manufacture of storage batteries, printing, painting and glazing china and pottery.

Copper, zinc, tin, brass and bronze considered separately are not dangerous, but the fumes and dusts arising from their amalgamation in industrial uses give rise to both respiratory and skin diseases. In any trade where the process of combustion takes place, such as the manufacture of steel, coke, cement and brick, the workers at the blast furnaces are exposed to carbon monoxide gas and occasionally suffer from serious nervous troubles as a result. In the manufacture of pig iron the inhalation of manganese fumes may contribute to illness. Particularly poisonous gases are liberated during the disintegration of ferrosilicon ores. This has on a few occasions occurred in the holds of ships carrying the ore, and the phosphureted and arseniureted hydrogen gases escaping have caused the death of sailors.

Since the World War there has been a great increase in the use of poisonous substances in industry, especially in the development in the United States of coal tar products yielding explosives, perfumes and dyes. Coal tar when subjected to fractional distillation yields benzene, toluene, naphthalene, carbolic acid and pyridine. Men exposed to the vapors of coal tar and its products and to dust arising from pitch suffer from gastro-intestinal troubles such as gastritis, from bronchial catarrh as well as from various potentially malignant skin diseases.

In addition to maladies produced by chemicals skin diseases may arise from parasites, infections, continued pressure on the skin and abrasions. One of the most serious parasitic infections occurs from the presence of spores of anthrax on wools, particularly those from Asiatic sources. If these germs are inhaled by the workers they cause an acute type of septic pneumonia, which often proves fatal within forty-eight hours. The infection is sometimes local, affecting a small portion of the body, and if early surgical measures are applied the disease may not be followed by constitutional symptoms. Machinists constitute another group of workers particularly prone to develop infections from their exposure to small sharp particles of steel or sprays of dirt laden oil, which reach abrasions in the skin and set up irritations.

Work in high temperatures is not only unpleasant but may also give rise to serious consequences to the health of the worker. The incidence of bronchial and pulmonary affections among blast furnacemen and textile workers is heavy, particularly in the latter trades, where moisture in the air is considered essential in the process of spinning the fibers.

Work in caissons used in modern bridge construction is carried on in compressed air in order to keep water out of the caisson. The process of decompression, wherein the workers go through air locks in which the pressure is gradually lessened, offsets the effects of the abnormal air conditions; but if decompression is hurried, pain and paralysis occur. The only preventive measure is strict adherence to the rules as to the length of time to be spent in leaving the caisson; treatment by recompressing and then slowly decompressing is successful unless hemorrhages into the central nervous system have occurred.

There are certain trades wherein the workers exhibit a high mortality rate from particular diseases which are not classifiable solely as industrial affections. Thus tuberculosis may arise in the case of workers made susceptible by the inhalation of dust, by employment in overcrowded and insanitary rooms or by an injury which weakens local resistance and makes tissues more receptive to the bacillus. The development of cancer after an injury received at work is coming to be recognized in some cases as explainable either because an incipient growth was already present at the time of receiving the injury or because the accident in some way or other altered the structure of the parts injured. Persons following certain occupations are particularly liable to cancer: in Germany the high incidence of cancer among gardeners and farmers suggests some relationship between malignancy and contact with earth. In England and the United States there has been observed a close relationship between a high mortality rate from cancer and work in tar and pitch as well as in trades where use is made of mineral oils.

Complete prohibition of a dangerous process is rarely possible, although it has been accomplished in a few instances where substitutes were easily available. This is true of the manufacture of lucifer matches; since the substitution of the sesquisulphide for the dangerous form of white phosphorus, necrosis of the jawbone no longer occurs among the workers. Hence the hygiene measures to be adopted in the case of the various maladies to which modern workers are subject

must be regulated in accordance with the special situation and depend primarily upon the method by which the injurious substance enters the body. Industrial poisons may be guarded against by individual or collective action. Dr. Alice Hamilton has added considerably to the literature of the subject and has suggested as the minimum in preventive measures the provision of bathing and laundering facilities in the factory; hot, nourishing food; and the protection of the skin by oils, powders and overalls. Periodic examinations, particularly of those employed in the more dangerous processes, are also essential. Individual protection is provided for workers exposed to both poisonous and non-poisonous dusts in the form of respirators or masks. Considerable controversy has arisen over the efficacy of the measures described above to say nothing of the inconvenience to the wearer. It is probable that collective action, offering continual means of prevention, would be more successful. Among these are the introduction of new processes, such as the use of closed receptacles where the treatment of the product can be carried on mechanically, and the use of sprays or running water to combat poisonous dusts. The latter measures have had a striking influence in reducing the number of cases of industrial lead poisoning, particularly in England. Other forms of collective action which are now quite generally adopted are the use of exhausts and the dilution of the dust by means of a ventilation system. If all possible methods of protecting the individual and of purifying the air are practised and injury still occurs, the only remedy is complete abandonment of the process or the shortening of exposure to the cause of illness.

THOMAS OLIVER

LEGISLATION AND REFORM. The movement for industrial hygiene has reached very different stages in different countries, with England and Germany standing first in the application of remedial legislation. The law requiring the ventilation of noxious gases was passed in England in 1855; in 1867 the removal of dust by mechanical means was first made compulsory. By 1890 the British Isles had passed measures demanding if not standardizing ventilation, heating, lighting and the like. From 1901 onward laws and orders with respect to dangerous trades were issued regularly, and an increasing number of trades were brought under the factory acts. One of the most effective devices for control in England is the compulsory notification of an increasing

number of industrial diseases and poisons. Enforcement is in the hands of factory inspectors. In spite of the great advances in certain trades, for example, the potteries and white lead works, enforcement is probably still inadequate to cope with the increasing problems of industrial illness.

Prussia took the lead over other German states in factory legislation with the factory act of 1839, which inaugurated the legal protection of the health and safety of employed children. Bismarck's opposition to general protective legislation retarded the movement in the nineteenth century, but in 1898 complete provision for the sanitation of lead storage battery plants was enforced by law. Later, particularly after the introduction of health insurance and workmen's compensation, ankylostomiasis, anthrax, benzene poisoning and other types of disease were thoroughly studied and brought under control by means of laws and orders. In Germany the expert qualifications of the factory inspectors are notable, and they establish their own hygienic standards in the process of enforcement to a much greater extent than inspectors in other countries.

Factory legislation of a desultory sort was introduced in France from 1813 onward, and that country holds the distinction of being the first European state to take male workers under its protection in the Hours Act of 1848. Factory inspection came in 1874. The hygiene and security law of 1893 marked a great advance by making detailed provisions for general factory hygiene and for dangerous processes. Special laws and orders for certain trades began under the labor code in 1913 and since the war the Ministry of Industry and Commerce has published a series of useful studies of poisons and diseases. Here too the matter of enforcement is in the hands of inspectors.

In the United States federal action has been taken in the case of phosphorus and anthrax and also in the form of suggested hygiene practises based on studies of specific hazards and published at intervals by the Bureau of Labor Statistics. Since 1930 the federal Public Health Service has extended its sphere to industrial hygiene. Most of the legal regulation has been of course in the hands of the states. Nearly all have legislated in behalf of women and children. Inspection and regulation of workshops and factories with respect to ventilation and sanitation are enforced by the department of labor in each state. State laws covering work in foundries, lead using industries, compressed air, mines, machine

shops and the like and demanding compulsory notification of certain industrial diseases vary according to the importance of the industry in the commonwealth. But it would be erroneous to suppose that health protection has reached its maximum efficiency in each state. The degree of legal regulation is in part influenced by the presence of workmen's compensation; and only a quarter of the compensation laws cover diseases and poisons, although probably every state contributes to the quota of industrial illness.

In universality and elaborateness of hygiene legislation Soviet Russia stands foremost among industrial countries. The labor code of 1922, which has frequently been amended, applies to all workers in industry. It limits hours in dangerous occupations to six, five, four or even three a day; provides special protection for women and children; makes compulsory protective devices, physical examinations and approval of new plants; and altogether prohibits the use of some poisonous substances, such as lead, in certain trades. Enforcement in each plant is in the hands of a factory committee, which is elected by the trade union members in the plant. Technical and medical inspection is under the control of the factory committee and the district trade unions. The bureau of public health cooperates with the industrial medicine section of the bureau of labor in its educational work. In spite of its elaborate legal structure, however, the merits of the movement for industrial hygiene in Russia are found in its inclusiveness and its excellent educational propaganda rather than in its effectiveness in actual practise. Lack of trained medical personnel and of experienced industrial workers has prevented the progress which would otherwise be expected under a complete and national system of control.

The movement began to take an international character toward the end of the nineteenth century, when the first international congresses, generally dealing with both diseases and accidents, were held in Europe. Among the periodical meetings at present are those of the International Congress of Industrial Diseases and Accidents and the International Congress of Pathology and Industrial Hygiene and the conferences of the International Association for the Promotion of Industrial Welfare, composed of factory inspectors. The most prominent permanent organization on an international scale is the International Labour Organization which, by means of special studies on occupation and health and its conventions offered for ratification to the various

member countries, attempts to secure advanced and uniform legislation in this field.

Private action in behalf of hygiene in industry has had its greatest development in the twentieth century, particularly since the World War. The initiative came from groups interested in social reforms, and the movement was carried forward by public health bodies and to some extent by private physicians and employers. The larger industrial countries now have research organizations, like the National Safety Council in the United States, the Industrial Health Research Board in England and the Institut d'Hygiène Industrielle in France, which are educational in character and publish periodical studies and recommendations.

The work of these semipublic bodies is retarded, however, by the slow recognition of the problem in schools of medicine and the consequent lack of cooperation in research and education. Many of the studies from the strictly medical point of view have come from the United States, where there are chairs of industrial hygiene in three universities and numerous courses in the subject. Several institutes for the instruction of physicians in industry exist in Italy and Russia; there are several chairs of industrial hygiene in Germany, one in France and one in Wales.

Action by private employers in the sanitation and hygiene of industry, as in other fields of labor relations, has been most marked in the United States. The Bureau of Labor Statistics recorded 430 plants in 1927 which maintained active hygiene departments with industrial physicians or nurses. The interest of employers in the movement was undoubtedly aroused as a result of the introduction of workmen's compensation laws, but at the present time the industrial physician has a definite professional status in industry. There are two national organizations composed of industrial physicians, whose purpose is to assist cooperation between different industries and between the private practitioner and the industrial doctor. Probably the chief reason for the greater number of industrial physicians and plant hospitals in the United States than in other countries has been the existence of large scale enterprise and the relatively low cost per worker of maintaining an elaborate medical organization. There is general agreement that for small plants the cost of special medical service is prohibitive, and the attempts to provide in the United States a cooperative service in certain localities have not yet attained great results. A further limit to initiative by employers in all

countries is the frequent opposition of the medical profession to the extension of the sphere of the industrial physician or nurse into the worker's home. At other times opposition arises from the employees, who fear that physical examinations and other medical work are discriminatory rather than remedial. Joint action by employers and employees has been effected only in the garment industry and in a few other highly organized trades in the United States, where trade agreements may contain regulations as to sanitation and protective devices to be furnished the worker; but on the whole the unions in both the United States and Europe have been noticeably ineffective in promoting the hygiene of industry by direct action.

The obstacles now facing the industrial hygiene movement obviously fall into three main divisions: lack of knowledge, lack of cooperation from interested groups and lack of power to introduce hygienic measures. There is a genuine difficulty in establishing the cause of a disease where the worker is exposed to more than one source of danger, but a hindrance to remedial measures which could be more easily removed is the indifference of the medical profession to education in the subject. Practical knowledge would also be aided by a thorough system of compulsory notification and workmen's compensation. In so far as the health of the worker depends on his home environment, his hours and wages, cooperation between the groups determining these factors and the industrial hygienist is essential. Finally, the difficulty of establishing adequate inspection and of keeping pace in legislation with the increasing number of dangerous processes in a complex industrial society still limits the effectiveness of the industrial hygiene movement.

INDUSTRIAL POISONS. *See* **INDUSTRIAL HAZARDS.**

INDUSTRIAL RELATIONS. The complex relations which now prevail between employers and employees in most industrial countries stand in sharp contrast to the simple arrangements which governed the relations between the boss or owner and his workers during the industrial revolution and for some time afterward. At the beginning of the nineteenth century the individual employer determined the law of industry for his particular plant, subject only to the vague control of the competitive system. The striking changes in industrial relations which have taken place since that time may at first glance appear to follow no uniform pattern in the various countries, but they reflect deep seated economic and social forces which have for a long time directed the course of the principles and practises of industrial relations in western Europe, Australia and the United States.

In the course of the evolution of industrial relations the autocratic power of the employer has been attacked from two directions. On the one hand, the workers have openly or tacitly asserted the demand to be consulted in the determination of the terms and conditions of work. Their ability to achieve recognition of this right has varied considerably with the various countries and with the different industries in the same country. But in every important industrial country attempts more or less advanced have been made to apply the procedure of democratic government to the conduct of human relations in industry. On the other hand, the government has tended to participate in industrial relations and to indicate in greater or less detail and over a varying area of industry the basic principles which must govern

in the arrangements between employer and employee. By means of collective agreements entered into between the workers and the employers and by means of legislative enactments the position of labor has been continuously redefined. The early attempts to define the status of labor were concerned primarily with wages and hours and with the protection of the life and health of the workers. Modern systems of industrial relations have become more and more concerned with elaborate definitions of the status of labor in the factory and in industry as a whole, with attempts to insure labor against the economic insecurities created by modern industry and with an infinite variety of devices for regulating the division of the product of industry and for redistributing the areas of industrial control. Wherever the modern factory and large scale production have come to dominate the industry of a country, an increasing number of rules and regulations fixing the conditions of work and defining the rights and duties of labor, management and ownership have gradually been formulated and accepted and have become the law of industry. The increase in this body of rules and law has necessitated the development of machinery for their interpretation and enforcement. In all industrial countries consequently relations in industry have come increasingly under the jurisdiction of judicial and administrative agencies created for the purpose of interpreting and enforcing the rules of industry. These agencies range in authority from the private arbitration court operating under collective agreements, as in the United States, to the public industrial court, such as that of Soviet Russia.

These developments in the practise of industrial relations are traceable in the main to the swift and revolutionary changes in the technique and organization of industry and to the spread of political democracy. It is impossible to assess the influence of each of these forces, but their combined effect has been to strengthen the position of labor and to limit the powers of management and ownership.

The rise of large scale enterprise and of vast industrial establishments, many of which employ directly hundreds of thousands of workers, has profoundly modified the traditional personal relation between master and servant or between the owner-manager and his few employees. The mere employment of large numbers of workers accustomed to the concept of universal political suffrage has tended to modify the practises adopted by industry under conditions of political

and industrial autocracy. Decisions as to wages or hours or work rules, formerly made in the course of personal conversation, now in many cases wait upon the canvassing of the public opinion of groups of employees, the exercise by them of their rights of industrial suffrage, negotiations between the representatives of employees and employers; in short, upon the application of the methods of representative government.

Much of the mass of rules which now govern working conditions is a direct outcome of technological factors peculiar to large scale industry. Mass production and mechanization demand perfect precision and smoothness in the operation of the plant. Frequent and prolonged interruptions to the even flow of work may exhaust a great part of the savings in cost gained by division of labor and mechanization. Effective management under such conditions involves not only the strict enforcement of detailed specifications for all conceivable types of jobs but the application of an equally important body of rules covering hours of work, tardiness, absenteeism, all matters of shop discipline and the division of responsibility between management and labor for the care of expensive and delicate machinery. In this development the introduction of scientific management has been a very important factor. Scientific management was originally designed to increase the productivity of labor directly by adding to the skill and improving the technique of labor and indirectly by the coordination and planning of the processes of production. But it soon became apparent that the success or failure of scientific management depended in large measure on the extent to which it was able to enlist the understanding and cooperation of labor. Industrial psychologists tended to stress the importance of labor goodwill and the relatively unproductive character of repressed servile workers. In connection therefore with the advance in the purely technical elements of scientific management, constituting a species of code of factory and managerial practise, substantial progress has been made in the substance and methods of industrial relations concerned with such items as the choice of the appropriate and effective incentives for work, protection against irregularities of employment, the determination of fair standards of time-study and the granting to the workers of some share in the determination of these and other matters.

The profound and perhaps lasting developments in industrial relations, however, represent a phase of the fundamental adjustments con-

stantly being made in the structure and functions of our business society. As such they reflect the impact of ideas, the influence of political forces and the rise of a variety of social and economic institutions. The most potent single force in shaping the course of industrial relations has unquestionably been the organized labor movement. Whatever the remote origins of this movement may have been, its purpose soon became that of improving human relations in industry by protecting the status of labor against the wilful and autocratic acts of management and by attempting to secure for labor a larger and more equitable share of the proceeds of industry. Labor organization thus became the instrumentality through which large groups of workers expressed their desires for a higher standard of living and a more effective voice in determining the policies of management. Limited in its early history to a small membership among workers in relatively few and selected crafts, the labor movement expanded rapidly after the middle of the nineteenth century; it grew at a faster rate than the total working population and penetrated into entirely new industries and occupations, winning adherents among the semi-skilled and unskilled and even among salaried employees and agricultural labor.

In spite of frequent setbacks due in the main to economic and political adversities the labor movement has continuously widened the area of its control within the countries in which it had already been established and has spread into countries where labor had been unorganized. By the first decades of the twentieth century organized labor was not only firmly established in the industrialized countries of the western world but had also achieved status and substantial influence in China, Japan and parts of India. Wherever the labor movement has taken root the methods and purposes of industrial relations have been revolutionized. The collective agreement has replaced the individual bargain. The issues subject to collective bargaining and hence to joint adjudication have grown in number and significance from simple rules fixing the fines for careless work to the relation between profits and wages and, finally, where organized labor has reached the height of its power, to plans involving the socialization of industry.

Few of these advances either in industrial relations or in trade unionism would have been possible if the masses of people had not been afforded the opportunity to employ their collective political power. In a sense the trend toward de-

mocracy in industry and the organization of labor is inextricably combined with the expansion in the political rights of the common people through the rise of political democracy and the granting of universal suffrage. The increasing political power of the workers has been exerted in two directions. Where the ideas of individual freedom and rights were most firmly implanted and the political power of the propertied classes was greatest, the political influence of labor was used to secure the right to organize and to act collectively. In many countries, including the United States, this struggle in the legislatures and courts to win the right of collective bargaining has been carried on for more than a century and has been in large part responsible for the creation by labor of its many political instrumentalities, varying from complete political organizations, like the British and Australian labor parties, to the more limited lobbying agencies of the American Federation of Labor and the American railroad unions. Where labor has succeeded in mobilizing its political strength, as in England, the status of the organized labor movement has been unequivocally established; but where, as in the United States, the separate and independent political organization of labor has been opposed by the official labor movement, the legal status of organized labor although markedly improved is still confused and uncertain.

Labor movements have used their political power in another direction to seek the solution of many of the problems of industrial relations by the passage of appropriate legislation. In addition to the law of industry which has grown up under purely voluntary arrangements between organized employers and employees an increasing number of the issues of industrial relations have been brought under the law of the land. The labor legislation of England and of Germany, for example, limited in its early stages to humanitarian provisions for factory inspection and to vague assurances of the right to organize, has now reached the point where the treatment of the complex problem of industrial unemployment has come to be regarded as a function of the state. In all countries the volume of labor legislation of similar character has grown by leaps and bounds and in some instances, notably Australia and the U. S. S. R., the legal regulations affecting industrial relations are of far greater significance than the provisions of private collective agreements. Where this change has occurred, the whole machinery of industrial relations has been revolutionized. The

issue of the equitable division of the income of industry has been raised to a position of first importance, and in negotiation and bargaining political pressure has replaced economic pressure as the instrument of the power of labor.

Intangible factors have played an important part in the swift universal acceptance of the system of ideas and practises and procedure embodied in prevailing plans of industrial relations. Of these the dominant influences would appear to be the tenacity of revolutionary or radical political doctrine and the expansion in the facilities of education and communication. Throughout the history of modern industrial relations and trade unionism the dissemination of revolutionary doctrine in all of its forms, preaching the inevitability of the class struggle and the essential incompatibility of the interests of various economic classes, has been the moving force in effecting greater unity among working class movements and in directing the channels of their thought. Even during the past several decades, when in some western countries, particularly in the United States and France, the idea of class cooperation or collaboration appears to have made some headway, the traditional radical doctrine still remains the dominant influence. To the slow and persistent influence of economic and political radicalism the revolutionary forces let loose by the World War gave an added impetus. The revolution in Germany and the brief industrial upheavals and attempts at syndicalist operation of industry in Italy together with the experiments in the peaceful socialization of industry pursued by the British Labour party during the 1920's had their repercussions on the thought and programs of labor movements the world over. The actual setting up of a workers' government in Russia, while it has resulted in doctrinal schisms among the radical organizations in other countries, has nevertheless furnished an object lesson to the many who, not satisfied with capitalist economic organization, look for a solution in the Russian measures of state ownership of property and the central planning and control of industrial operations.

The universal character of trends in industrial relations is plainly attributable in considerable measure to the growth of mass education and to the development of facilities for the prompt communication of ideas. The ability to read newspapers and the circulars, journals and reports of trade unions, not to speak of the simpler texts on social and economic problems, accounts for many of the ideas held not only by the leaders

but by an increasing proportion of the rank and file of labor. The typical program in industrial relations today is an amalgam of the conclusions drawn from practical experience and generalizations gleaned from reading the views and experiences of others. The extent to which the revolutionary improvements in the facilities of communication have contributed to the creation of a common fund of experience and ideas in the field of industrial relations is indicated by the profound influence which the English and German experiments with unemployment insurance have in less than ten years exerted in America and by the world wide attention and study which have been focused on the hopes and achievements of the Soviet Five-Year Plan. Direct international educational contacts have also contributed to the wide diffusion of systems of industrial relations. The tendency of industrial relations in the Orient to follow the patterns of the Occident is due in some measure to the fact that the large number of oriental students who secured their education in the institutions of higher learning of the West carried back to their own countries the economic doctrines and the programs of social reform which they learned there.

Another factor contributing to the change in industrial relations has been the reawakened interest of various religious organizations in the status of the worker. The famous encyclical letter of Pope Leo XIII *On the Condition of Labor*, issued in 1891, has been the basis of the modern Catholic attitude toward trade unions; its basic principles were restated in the papal encyclical of 1931. The Central Conference of American Rabbis and the Union of American Hebrew Congregations have frequently expressed their interest in the problems of industrial relations, and the Federal Council of the Churches of Christ in America has sponsored studies of particular situations of conflict between employer and employee.

Despite all these forces it is probable that changes in industrial relations would under ordinary circumstances have occurred at a much slower rate than was actually the case. The economic and social consequences of the World War were principally responsible for an acceleration in pace and possibly a revision in emphasis. For the first time in modern history the leading nations of the world were forced to mobilize their entire military and industrial resources with unprecedented speed and thoroughness. The interdependence of the military and industrial machines was greater than ever before.

Even the slightest interference with industrial plans might have had serious consequences at the front. Such a vast program could obviously not be successfully carried through without the utmost cooperation and support of labor. To win this support the governments of many of the belligerent nations embarked on what may be described as a new labor policy. They granted official recognition of the right to collective bargaining. They set up industrial boards, containing representatives of labor, charged with the exercise of a large measure of industrial control. They took more than a sympathetic interest in the problems of labor. Economic forces were meanwhile likewise contributing to the growth of labor organization. The lag of wages behind prices and the cost of living, which were mounting swiftly to twice their pre-war levels, produced general unrest. The great burst of business activity and the withdrawal of millions of able bodied men from industry resulted in a universal shortage of labor. The combined effect of these favorable economic and political conditions was to add to the numbers, power and prestige of all labor movements. Between 1914 and 1920 trade union membership in the world more than doubled.

With this growth in numbers and influence came the first taste of power and responsibility. Representatives of labor were admitted into the councils of government. They participated in decisions of vast import. They proposed experiments in industrial management and saw them put into operation. Where the exigencies of war brought about the public operation of private industries, labor for the first time shared in the determination of basic policy and in the processes of management. This experience compressed within the short space of five years freed the imagination of labor leaders and of their followers, gave them a fresh conception of their place in industry and enabled them to look forward to the swift adoption of programs of genuine industrial democracy. The impetus given these movements by the war continued into the early post-war years, sustained in part by the hopes generated in the past and in part by the favorable economic circumstances arising out of the brief post-war boom in business.

In essence the war experiments in industrial relations represented efforts to extend the area of collective bargaining and to secure for workers "a greater share in and responsibility for the determination . . . of the conditions under which their work is carried on." In the United States

the first end was accomplished by the doubling of the membership of labor organizations and the adoption of manifold systems of collective bargaining in industries in which labor had hitherto had no organized voice in determining working conditions. The tendency toward greater industrial democracy was furthered in a variety of ways. Industrial relations in industries under complete government control, like the railroad system during the period of government operation, were administered by specially created labor boards, highly sensitive to the wishes of labor and eager to promote experiments in labor control. In the Rock Island government arsenal a far reaching attempt at joint management was actually initiated. As an aftermath of the war experiments the term industrial democracy came into common usage and the powerful railroad unions in 1919 went so far as to propose the famous Plumb Plan, a project for the reorganization of the railroad industry and its subsequent operation under the joint management of labor, capital and the public. Yet with all the wartime growth the total number of workers organized in trade unions in the peak year, 1920, was only 5,110,800. This represented somewhat less than 20 percent of the total number of wage earners—slightly more than 20 percent if agricultural workers are excluded. The so-called company unions covered only relatively few workers at that time. Thus even at the peak of labor organization in the United States over three fourths of the wage earners still had no organized voice in fixing the terms of their labor contract.

Developments in England during the war pursued a course similar to that in the United States. Under the aegis of the government and assisted by prosperous conditions the trade unions extended their jurisdiction and their power. Union membership reached the unprecedented figure, for Great Britain, of 8,328,000 in 1920, the peak year. This represented well over 40 percent of the wage earners of the country. Within the ranks of labor aspirations for control took a variety of forms and finally assumed considerable vitality in the demand for decentralization in the management of industry, reflected in the rise to a position of temporary importance of the shop steward movement, a revolt at once against autocratic control by management and centralized control by the trade unions. The government attempted to stimulate joint control of industry. It sponsored the Whitley report in 1917, which proposed setting up joint industrial councils with equal representation of employers and em-

ployees to achieve among other things "the better utilization of the practical knowledge and experience of the work people" in the conduct of industry. Observers of all sorts, viewing the English war and early post-war advances in industrial relations, did not hesitate to regard the progress already made as the forerunner of the immediate democratization of English industry.

On the continent there has been a greater diversity of experience. The German government, like all war governments, saw the necessity of enlisting the sympathetic support of labor and its organizations, which had been strictly limited in their activities before the war. The revolutionary change in the status of German labor and in the machinery of industrial relations dates, however, from the establishment of the republic. The republican government, the product of a revolutionary movement, in which the labor and socialist movements were at the outset at least among the most conspicuous participants, undertook to restate the terms of labor relations. In the Weimar constitution accordingly the principles of works councils, created by the German Works Councils Act of February 4, 1920, were defined. While these councils are composed solely of employees and are purely advisory bodies, their right to require a great range of information on the operations of business and to be represented on the boards of control of industry paved the way for the development of genuine joint industrial control. In Germany as in England, however, the most substantial advances in labor relations came by way of the traditional devices of collective bargaining and legally recognized collective agreements between the long established and experienced trade unions and the various employers' associations.

The course of events in the young industrial countries Australia and Canada during the war reveal no radical variations from this general picture. Industrial relations in Canada, greatly influenced by tendencies in the United States and largely carried on between Canadian industry and American labor organizations, experienced little change in their essential character during the war. In Australia the system of government arbitration courts, comprehensive labor legislation and collective bargaining, firmly established in the six states before the war, was substantially strengthened and extended under the influence of a strong labor movement and the independent political power of labor. Assisted by war prosperity, a friendly government and a vigorous trade union policy the rights of

Australian labor became more deeply entrenched and the conditions of labor vastly improved.

Economic and political readjustments following the war have served to test the validity of war experiments in industrial relations and to reveal the problems of the future. After the post-war boom from 1918 to 1920, during which prices and business activity ascended to unprecedented heights, the business of the world entered in the depression of 1920 upon a period of drastic and prolonged economic readjustment, interrupted in some countries by spells of prosperity of varying duration. In both internal and foreign markets the competition for business has been carried on with increasing intensity. Labor and other costs of production have again risen to the position of paramount importance in business calculations which they occupied before 1914, and which they apparently lost during the war. The consequent movement for lower costs has in the view of the owners and managers of industry encountered insurmountable obstacles in the inflexibilities of the wartime systems of industrial relations and in the rigid standards of wages and working conditions. Since 1920 then the struggle over the powers of management and the respective shares of the income of industry has been fiercely waged, and the methods used have been tempered only by the realization on the part of management that rights and powers once surrendered cannot be completely regained.

The nature and consequences of this struggle are exemplified in the post-war developments in industrial relations in the United States. The scrapping of the war machinery of industrial control and labor representation was followed during the depression of 1921 by frequent conflicts between organized labor and employers. No longer able to count on government support and faced in many instances by hostile courts the labor movements suffered severe defeats, losing all control in many industries and appreciably weakening in others. Industry therefore entered the decade of the twenties free to pursue its own policy and to return, if it so desired, to paternalistic methods of management. But the ideas and procedures implanted during the war could not be so easily uprooted. The desire on the part of the workers for a larger measure of industrial democracy had apparently come to stay. The management of industry exercised its ingenuity in the invention of measures designed to insure the rights of labor to consultation and to participation in the councils of industry and at the same time to preserve

freedom from trade union control. The whole series of measures, commonly described as welfare capitalism, reached a high stage of development during this first post-war decade. Their essence was class collaboration, or cooperation between employers and employees. In the machinery for the administration of these measures many industries set up their own plans of joint industrial councils, encouraged employee stock ownership, provided a range of welfare services and insurance and in some few cases even undertook to deal effectively with the problems of irregularity of employment. These measures flowered during eight years of prosperity, and although they appear to have contributed little toward the redistribution of the wealth and income of the country they have shown considerable vitality and have been effective in retarding the growth of organized labor.

The trade unions on their part underwent a similar reaction in methods and purpose. Programs of industrial democracy were abandoned soon after 1920. Moved by their experience with management, a cooperative movement sponsored by organized labor and taking the form mainly of the organization of labor banks was launched by individual trade unions. With few exceptions, however, these excursions into the field of labor ownership had collapsed by 1930. The pendulum indeed had swung to the other extreme. Under the stress of adverse economic conditions the labor movement was forced to adjust its conceptions of industrial relations and began its post-war experiments with labor-management cooperation. Notably in the clothing and hosiery industries and in the railroads the unions undertook to meet the problems created by falling prices and severe competition by accepting a larger measure of responsibility for industrial costs, by applying the technical knowledge of workers to the reduction and control of wastes and by experimenting, in rare instances, with the operation of factories owned and managed by labor itself.

These post-war problems and experiences in American industry proved to be common to all capitalistic countries. Nearly everywhere the labor movement lost a large part of its war gains in membership. The political power of labor, however, has acted particularly in Europe and Australia to retard the processes of reaction and to force consideration of vital changes in the ownership and management of industry. The English labor movement, despite its losses in membership, was able through its industrial and

political strength to retain a large measure of its power in English industry. But here also the force of persistent industrial depression and prolonged unemployment accounted finally for the crushing defeat of the British Labour party in 1931. Present tendencies in English industrial relations are apparently moving in distinctly opposite directions. On the one hand, the disappointment of labor with the achievements of the Labour party and what labor regards as the breakdown of capitalistic business have given rise to a strong movement within the ranks of labor for the swift and general socialization of industry. The influence of immediate events, on the other hand, is in the direction of the adaptation of the instruments of collective bargaining and industrial relations to prevailing economic conditions and the encouragement of further cooperation in industry of the sort proposed in the Mond-Turner conferences on industrial relations in 1928. Trends in Australia appear to be following the same pattern. There public budgetary difficulties and a high rate of unemployment arising out of the loss of a substantial part of Australian foreign trade have already resulted in the weakening of the labor parties and in efforts to limit the scope of state interference in industry, to achieve thereby greater flexibility in the settlement of the issues of labor relations.

In France and Italy radical wartime developments similar to those in other countries were dissipated in the post-war reaction. In France there was on the one hand a return to ordinary collective bargaining and on the other a development of a paternalistic and individualistic system of industrial relations, reminiscent of the state of affairs in many American industries. In Italy the reaction brought to a head by the establishment of the Fascist government produced a plan of industrial relations which, while it seems to differ from those in effect in other capitalistic countries, is substantially of the same species. The foremost industrial problem that at the beginning confronted the Fascist government was to procure peace and cooperation in the conduct of Italian industry. The achievement of this end involved the stamping out of traditional trade unionism and radicalism and the substitution of a system of industrial relations based on cooperation and class collaboration. Such a system, providing for the organization of occupational and industrial syndicates promising joint industrial control, was projected by the Italian government and has since seen some modest development under the strict supervision of the state.

Only in Germany and Russia do the prevailing systems of industrial relations differ radically not only from the pre-war and war models but from the plans in force in other countries as well. In both countries the present relations in industry are the product of political revolution. The building of a new industry and a new social system in Russia and the necessity for the drastic readjustment of German industry to a changing world economy, complicated by the tremendous problem of reparations, have imposed upon the governments of both countries the obligation of exercising extensive control over the operations of industry. The technical difficulties involved in increasing the productivity of industry in Russia have raised in the administration of Russian industrial relations the problems of reconciling the power of labor with its responsibilities in socialized industry. The perilous economic condition of Germany and the rebellious state of mind of German labor have raised a similar problem of tiding competitive industry over the dangerous rocks of depression while at the same time protecting the rights and privileges of labor.

The tendency toward ever greater representation of the workers in the affairs of industry, greatly accelerated by the war and the political upheavals following it, has in most countries apparently been not only stopped but actually somewhat reversed by the post-war reaction. But the trend toward the application to industrial relations of the procedure of democratic government appears irresistible. The most interesting and important problem in industrial relations is how soon this tendency will reassert itself and whether it will return to its pre-war rate of progress or to some accelerated rate created by new and powerful factors.

INDUSTRIAL RELATIONS COUNCILS.

Two main types of industrial relations councils have developed during and since the World War: statutory works councils whose scope and functions are defined by legislation and voluntary works committees or councils set up by mutual agreement between workers and employers.

At the present time statutory works councils are to be found in Germany, Austria, Czechoslovakia and Norway. The German Works

Councils Act of 1920 represented in part a continuation and extension of the earlier system of workers' committees, legislative provision for which had been made in a permissive form in 1891. In 1905 the establishment of such committees was made compulsory in the Prussian mining industry and later in the industry throughout Germany for all undertakings employing more than 100 workers. Their powers, however, were strictly limited and their practical importance was not great. The World War gave a decisive impetus to the trade union movement, which hitherto had been struggling for recognition; and when the need for expanding the output of munitions led to the passing of the Auxiliary Service Act in 1916 the unions were able to secure the constitution of workers' committees in all undertakings coming within the scope of the act and employing more than 50 workers. In the event of disputes with the management these committees had the right to the appointment of conciliation boards (*Schlichtungsausschüsse*) which were empowered, failing a settlement by agreement, to make decisions binding on both parties. Finally in December, 1918, an order was passed which besides giving legal recognition to collective agreements (*Tarifverträge*) provided for the organization of workers' committees in all establishments employing 20 or more workers. At this stage a new factor was introduced into the situation through the permeation of a part of the German labor movement by revolutionary ideas from Russia. The success of the Bolshevik revolution was universally associated in the popular mind with the councils of workers, peasants and soldiers on which the Soviet system was based. There was a widespread reaction in Germany against parliamentary government and the centralized state and in favor of a more syndicalistic type of politico-economic organization. An armed revolt of Spartacists and other Left wing adherents broke out early in 1919; although it was crushed by the forces of the republic, there remained a strong sentimental attraction toward some form of councils system. This received official if somewhat reluctant recognition in the constitution of Weimar of July 31, 1919, article 165 of which provided for the establishment of a hierarchy of workers and economic councils involving an elaborate system of occupational representation side by side with the political representation centered in the Reichstag.

The immediate sequel to this was the passing of the Works Councils Act of February 4, 1920.

According to this act works councils are composed of the employees alone and are to be elected by a form of proportional representation in all establishments employing 20 or more workers. Membership of the council ranges from a minimum of 3 where fewer than 50 persons are employed up to a maximum of 30 where there are 15,000 or more employees. In small establishments with from 5 to 19 employees a works steward may be elected. An important distinction is made between wage earners and salaried employees, each of which elect separately councils that have exclusive competence in matters affecting their special separate interests; but when the two sectional councils sit together on matters of general policy they form the works council of the establishment. The works council is elected for one year by secret ballot and there is no provision for recall during the legal term of office, although power is given to the labor courts to dissolve a council or to revoke the mandate of individual members in the event of gross abuse of their powers. The office of works councilor is an honorary one; but any loss of working time due to the exercise of official duties is required to be made up by the employer, who also finances the administrative expenses of the council. In many of the larger undertakings it is the practise for one or more members of the council to be released entirely from productive work while receiving the normal earnings from the employer. The German works councils unlike the Austrian cannot invite or collect subscriptions from the employees for any of the purposes of the council.

Except in large integrated concerns, such as Friedrich Krupp, A.-G., at Essen, where there are numerous works in close proximity to one another, and in state undertakings no provision is made for any superstructure built up on the individual works councils. In the former case a central works council for the whole concern may be elected by the works councils of the separate establishments from among their own members. Of the latter type the outstanding example is the federal railways, where there are not only local works councils but also district councils and a central works council for the whole railway system, the members of which are elected by the whole body of railway employees.

The main functions of the works council as laid down in the law are: cooperation with the management in the promotion of industrial efficiency and in the introduction of new labor methods; promotion of industrial peace within

the establishment; supervision of the execution of collective agreements; the securing of agreement upon works rules with the employer or, failing agreement, appeal to a conciliation board; cooperation with the factory inspectors in the prevention of accidents and the promotion of works hygiene; cooperation in the administration of works welfare schemes. The functions of the sectional councils are similar but more detailed and relate to the separate interests of either the wage earners or the salaried employees. In one respect very important powers are given to the sectional councils and not to the works council as a unit: an employee who has been dismissed may protest to his sectional council against his dismissal. If the council comes to the conclusion that his protest is justified but is unable to persuade the employer to rescind his decision, it may appeal to a labor court, which can take evidence on oath. If the court rules that the dismissal was unjustified it can compel the employer to choose between the alternatives of reemploying the man or compensating him on a scale fixed by the court. The members of the works council enjoy a special protection against victimization, for they cannot normally be dismissed except with the concurrence of the council itself or, failing that, with the concurrence of a labor court.

Two important limitations to the powers of the works council should be noted. First, the management of an undertaking is solely responsible for carrying out any decision arrived at in cooperation with the works council, and the latter has no right to issue orders on its own initiative or to interfere with the executive functions of the management, nor can it require the employer to follow its advice in regard to the conduct and organization of the business. Secondly, the works councils are subordinated to the trade unions in the sense that a collective agreement always takes priority over a works agreement, and the general regulation of wages and hours of work lies outside the scope of the works councils.

The works council is Janus faced: on the one hand, it must assume the responsibility of furthering the production efficiency of the enterprise and thus of cooperating with the employer in every way calculated to increase productivity in the collective interest; on the other hand, it represents the interests of the employees as an occupational group over against the employer. In order to fulfil the first of these duties the works council is endowed with considerable and

novel powers. It has the right to elect one or two members with full voting powers to sit on the supervisory committee (*Aufsichtsrat*) whenever the undertaking is organized in the form of a company; to require the employer in all businesses above a certain size to submit a quarterly report on the position of the undertaking; to have access to wages books and other sources of information necessary to ascertain whether the employer is carrying out the terms of collective agreements; to require the presentation of a balance sheet and profit and loss account with suitable explanations of their items.

The Works Councils Act came into force during a period of great political, social and economic confusion. During the first few months a determined attempt was made by the adherents of the soviet or council system to capture the works councils and so secure in the field of industrial representation that decisive control which had been denied to them in the political sphere by the adoption of the Weimar constitution on July 31, 1919. From the resulting struggle the great trade unions emerged victorious and assumed an effective control over the works councils which they have never lost, although the attempts of the Communists to capture the councils have never entirely ceased and always threaten to become a serious menace in times of acute industrial and political dislocation such as prevailed in 1930-31. There was therefore in the early stages a certain amount of distrust between the trade unions and the works councils which the former were afraid might act as a disruptive force inside the labor movement and weaken the leadership of the unions in matters of general policy. This distrust was strengthened not only by the endeavors of the Communists but also by the tactics of the employers who sought to make with their works councils individual agreements not in conformity with existing collective agreements. The unions, however, eventually succeeded in incorporating the works councils within their organization and in making them a source of strength rather than of weakness. Experience has shown that works councils of this type must be in a sense agents of the unions or at least must work in close cooperation with them if they are not to prove powerless in face of the employers or to fall victims to syndicalist tendencies. The works councils have reacted in three main ways on the development of the German trade union movement: they have strengthened the tendency toward industrial unionism as opposed to the older type of craft

unionism; their practical experience has helped to direct the attention of the unions toward previously neglected problems of production; and, thirdly, the councils have helped to throw up a new type of leader, in closer contact with the workers, with a better understanding of both their requirements and their weaknesses.

At the outset the works councils were undoubtedly a source of additional friction and disturbance in industrial relations, but as the revolutionary wave ebbed they came increasingly to serve rather as a stabilizing factor. Their effective power over against the employer depends mainly upon the broad economic factors which determine the relative bargaining strength of labor and capital. In particular they are dependent on the power of the trade unions which stand behind them. Actual relations within any given undertaking depend very largely on the personalities and characteristics of the employer on the one side and of the members of the works council on the other. In practise in the great majority of cases the relations are satisfactory and mutually beneficial.

As might be expected the achievements of the works councils on their more constructive side—e.g. cooperation with the employer in increasing productive efficiency and with the factory inspectors in promoting works hygiene and preventing accidents—have been comparatively slight. This has been due partly to the intrinsic difficulty and novelty of many of the duties laid upon the works councils, partly to lack of expert knowledge on the part of their members, partly to the unwillingness of the employers in many cases to cooperate wholeheartedly with the works councils and partly to opposition from the employees toward any change in conditions of work to which they have become accustomed. The first three of these reasons, to which might be added the frequent change of personnel resulting from the annual elections to the councils, serve also to explain the very slight use hitherto made of the right to inspect balance sheets and profit and loss accounts and to serve on the boards of supervision of companies.

The experience of more than eleven years' operation of the German Works Councils Act shows that, although the councils have not fulfilled the hopes entertained by the socialists during the immediate post-war years, their practical value and significance are to be found in four main directions. First, in the larger undertakings throughout the country the works council constitutes a most useful standing committee with

statutory rights and duties representing the interests of the employees, with which the employer can negotiate as a responsible body. Secondly, the councils have made extensive use of their powers to protect the workers from unjust and arbitrary dismissals and have secured for them in such cases compensation amounting in the aggregate to very considerable sums. Thirdly, the existence of the councils in a statutory form combined with the right of appeal to labor courts in case of dispute has done something toward bringing the rule of law into the work place. It is no doubt still a far cry to the "constitutional factory," but the autocracy of the employer is no longer as absolute as formerly.

Finally, the works councils are making a really important contribution toward the education of the German worker, partly through the number of those who have gained practical experience as members of works councils—a partial census in 1930 covering 46,299 establishments employing 5,900,000 employees showed that there were 156,145 wage earning works councilors—and partly through the notable stimulus given to the trade unions to provide special educational facilities for works councilors.

The German legislation providing for workers' representation has been more far reaching than any other in central Europe, but the first Works Councils Act was passed by Austria in May, 1919. In the majority of its details the law is very like the German, but it differs in certain outstanding respects: the expense of the councils is a charge upon the workers; it excludes from under its jurisdiction government employees, who are covered by special decrees; and it does not attempt to provide for even a slight share in plant management. Relations with the trade unions in Austria have been friendly from the first and permanent trade union members are permitted on works councils. More detailed and far reaching than the Austrian act but hardly as effective as the German legislation, the first Czechoslovakian Works Councils Act of February, 1920, applied only to mines and allied enterprises; it was later extended to include all other commercial and industrial enterprises. The Norwegian Provisional Act of July, 1920, is much less ambitious than the legislation on the continent and is neither automatic nor compulsory. Works councils may be set up in enterprises with more than 50 workers, where at least one fourth desire representation; rights of works councils are of an advisory nature only.

In England works committees existed before the World War in a generally recognized form in the mining and printing industries, while in a number of industries there were shop stewards, who were delegates of the trade unions inside the individual works. But in the engineering and allied trades there had also developed a shop steward system which was unofficial in the sense that the shop stewards, being elected by the whole body of men in the works and not by the unions, were responsible to the men and not to the unions and were frequently recognized neither by the unions nor by the management. During the war there was a great development of this latter type of labor representation, due, first, to restrictions on the right to strike which weakened the influence of the trade unions; secondly, to government legislation providing for the "dilution" of skilled labor with unskilled and in munition works with women's labor, which involved direct negotiation with the employers in the individual establishments; thirdly, to the great extension of the piecework system under conditions without parallel before the war; and, fourthly, to the administration of welfare schemes, war charities and the like. But in addition to these purely local bodies there grew up a militant shop steward movement which went far beyond the bounds of the individual factory and came to play a considerable role in certain important industrial areas. The chief center of this movement was on the Clyde, with subsidiary centers in Sheffield and Coventry. Here it took the form of a revolt against the leadership of the trade unions and was definitely revolutionary in character. In each of these districts during 1915 and 1916 workers' committees were set up composed of unofficial shop stewards from the different works and intended to coordinate action throughout the district. The leaders under the influence of that mixture of syndicalist and guild socialist ideas which had been so prevalent before the war were advocating a complete reconstruction of the industrial system on the basis of workers' control. But the driving force of the movement derived from the great discontent of the workers with the wartime restrictions on the freedom of action of labor and from the revolt of the rank and file against the support given by the leaders of the craft unions to the government measures for the prosecution of the war. During the later stages of the war the militant shop steward movement, drawing fresh strength from the Russian revolution, became increasingly entangled in political crises,

notably in an open hostility to the prolongation of the war; but its influence was mainly confined to the centers referred to and did not spread to the bulk of British labor. In May, 1919, an agreement was made between the engineering employers and trade unions, recognizing the existence of shop stewards elected by trade unionists within the works and providing for the establishment of joint works committees, consisting of not more than seven shop stewards and an equal number of representatives of the employers. The subsequent prolonged depression in the engineering industry and the great amount of unemployment have, however, driven the whole movement into the background and deprived it of the strength which it enjoyed under the abnormal wartime conditions. The shop steward movement has not played an important role in other British industries, and such works committees as exist (apart from a few set up under the Whitley scheme) are to be found in certain large firms, such as Cadbury Bros., Ltd., Imperial Chemicals, Ltd., Hans Renolds, Ltd., and others, where they have been set up on the initiative of the management.

The general ferment of ideas during the war, the widespread demand on the part of many employers as well as employees for a larger measure of industrial self-government, the reaction against centralized state socialism, the influence of wartime control of industry and the ardent desire of the nation that the end of the war should usher in a new era of industrial peace—these were among the motives which led the British government in 1916 to appoint a strong committee under the chairmanship of the speaker of the House of Commons, Whitley, "to make and consider suggestions for securing a permanent improvement in the relations between employers and workmen." The outcome was the establishment of Whitley councils—the formation within an industry by voluntary agreement of a National Joint Industrial Council representing the organizations of employers and employees in the whole industry: a sort of industrial parliament meeting regularly and discussing every kind of problem affecting the interests of those engaged in the industry. The Whitley Committee had also recommended the formation of district industrial councils and of joint workers' committees, but neither of these proposals has been put into practice to any appreciable extent. A large number of Whitley councils was formed within a short time and by 1922 as many as 73 were working, but many of these

did not survive for more than a year or two and by 1925 the number had fallen to 43. In December, 1930, there were 42 in operation. Whitley councils are mainly confined to industries in which machinery for conciliation and arbitration of the old type did not exist; they are not to be found in the cotton, coal, iron and steel, ship-building and engineering industries. On the whole they have done useful work in maintaining good relations; but they seem to have been most successful in those cases, such as the boot and shoe and pottery industries, where they have deliberately excluded wage negotiations from their sphere of activities. Where the councils consider wages this vital question tends to monopolize attention to the detriment of other matters and also commonly tends to harm relations between the two parties on the council. The decisions of a Whitley council, even when unanimous, are not binding on those engaged in the industry, and this fact has led to a certain amount of agitation for statutory enforcement; but hitherto the opposition to any legal recognition of agreements arrived at by the councils has been strong enough to prevent the government from adopting this proposal. It is noteworthy, in view of the official origin of the scheme for Whitley councils, that the state itself at first refused to adopt the plan for its own employees and eventually only did so under pressure and in an attenuated form.

A further development of the idea of voluntary cooperation between the two great parties in industry took place in November, 1927, when a group of leading industrialists headed by Lord Melchett (then Sir Alfred Mond) invited the General Council of the Trade Union Congress to enter into discussions with the aim of securing a closer cooperation between labor and capital in the task of reorganizing British industry. As a result the Mond-Turner Conference came into being and in July, 1928, a unanimous interim report was issued. After a preliminary declaration that the support and goodwill of the trade unions were essential to industrial reorganization the report made a number of concrete recommendations dealing with such matters as recognition of the trade unions affiliated to the congress, victimization of trade unionists, rationalization and similar matters. Its most striking proposal, however, was for the creation of a National Economic Council composed of members of the General Council of the Trade Union Congress and of an equal number of employers' representatives to act as a parliament for all

industry throughout the country, although only with advisory and consultative powers. Partly owing to constitutional reasons the two great organizations of British employers declined to adopt the report, and with the intensification of the economic crisis and the death of Lord Melchett negotiations were suspended.

In the United States impetus was given to the voluntary works council, or "employee representation," by increased production demands due to the entry of the country into the World War. Introduced by the government in certain war industries as an emergency measure, industry gave the system scant attention until after the war. Then the opportunity it afforded for non-union collective dealing was taken advantage of by many companies. Between 1919 and 1926 the number of works councils increased from 200 to 900, the number of companies having such councils from 145 to 432 and the number of workers from 400,000 to 1,370,000. In 1926, 58 percent of these workers were concentrated in 16 undertakings, each employing 15,000 persons or more.

The employee representation movement was probably influenced by the experience of the English Whitley councils, but it developed only in single establishments or in groups of plants under the same management. There have been only a few instances in the entire country of industrial councils composed of representatives of different firms in the same industry. The most striking difference, however, between the English and the American systems is the position of the trade union in relation to the works councils. In England the trade union, supplementing the works council, is the recognized body with which employers negotiate. In the United States except in a handful of establishments the works council is permitted no association with the trade union, from which the management—particularly when it initiates employee representation—will brook no interference. In the United States the works council as a rule is but a local, isolated and comparatively powerless substitute for the trade union in matters of paramount economic importance to the worker. That is why the American Federation of Labor, although in 1918 it favored the movement that was to have been modeled on the Whitley system, has since denounced employee representation as an attempt to break down the strength of the unions and prevent their further development and as a menace to genuine collective bargaining.

All of these varied movements and measures represent attempts to achieve what is vaguely termed by some economic self-government, by others economic democracy, by others workers' control of industry. These vague phrases embody strongly felt aspirations—on the part of many employers for more freedom in the control of industry in relation both to the state and to their own employees; on the part of the workers for a greater voice in the determination of industrial policy and of their own working conditions. Such changes as have taken place down to the present have gone only a very short way toward satisfying such aspirations, and it is abundantly evident not only that these are in many cases mutually irreconcilable but also that very great difficulties inherent in the nature of the state itself and of modern capitalistic industry must confront any attempts to bring about far reaching developments in these directions.

INDUSTRIAL REVOLUTION is the name given to those economic and technological developments which gathering strength and speed during the eighteenth century produced modern industrialism.

As a label it is admittedly unsatisfactory. One writer calls it "an unhappily chosen epithet for a singularly constructive epoch" (Beales); another doubts whether the term, "though useful enough when it was first adopted, has not by this time served its turn" (Unwin); Lipson occasionally puts it in inverted commas. The chief objection is to the word revolution. Yet that use goes back to the period to which it is applied. Yarn making machines, coke smelted iron, Watt's engine and Wedgwood's ceramic triumphs were described by contemporaries as "great and extraordinary," "most wonderful"; their effects must be "beyond the power of calculation." The steam engine would "produce great changes in the appearance of the civilized world"; and "a revolution is making," said Arthur Young in 1788 when he saw the textile machines spread from the cotton to the woolen industry. Frenchmen after 1789 naturally used the word even more freely in reference to changes in technique, organization and commercial policy; and it became part of the socialistic vocabulary. Blanqui in 1837 declared that by the revolution industrial conditions in England had been more profoundly transformed than at any period since the beginnings of social life. Engels used the word in 1845, and the Marxian thesis was that the technological revolution had transformed the economic and social structure and would do the same to political and intellectual life. Toynbee knew Marx' *Capital*, had studied the German socialist movement and was undoubtedly influenced thereby in his use and understanding of the term he put into academic circulation. Mill and Jevons also spoke of revolution; and in 1852 Michael Angelo Garvey, an English barrister, published a little volume called *The Silent Revolution*, which dealt with the effects of steam transportation and the telegraph on "the condition of mankind."

To Toynbee the use of the word seemed en-

tirely justified. He envisaged a peaceful eve followed by a stormy dawn. Prior to 1760 the "old industrial system obtained"; industry was in the hands of small independent master manufacturers who combined farming and industry, employed a journeyman or two and trained an apprentice. Between master and man was a "warm attachment"; the employee was the "cherished dependent." The class of capitalist employers was "as yet in its infancy"; there was some putting out of materials by merchants to be worked up in the operative's home, and a few large factories were in existence. But small scale organization predominated, and the gulf between employer and wage earner was narrow. Over this "quiet world" of "scarcely perceptible movement," this "slowly dissolving framework of medieval industrial life," hung the comprehensive code of state regulation of production, trade and distribution. Internal free trade had come in Great Britain, but foreign and colonial trade were fettered and free movement or enterprise was checked.

This old order "was suddenly broken in pieces by the mighty blows of the steam engine and the power loom," the spinning machines, the improved roads, the expansion of domestic and foreign trade and the *Wealth of Nations*. The "two men who did most to bring [the revolution] about were Adam Smith and James Watt"; aided by the other inventors, they "destroyed the old world and built a new one." A period of "economic revolution and anarchy" resulted, in which productive methods changed, economic beliefs were revolutionized and the state swung over from regulation to laissez faire. Population was "torn up by the roots" and, like industry, was dragged "from cottages in distant valleys into factories and cities," there to become a collection of hands, "the living tool, of whom the employer knew less than he did of his steam engine." Population grew rapidly in numbers, but the number engaged in agriculture declined both relatively and absolutely; the factory system became the "all-prominent fact" in industry; overproduction and depressions—"a phenomenon quite unknown before"—became normal

parts of business life; landlords and manufacturers waxed rich, but the wage earner fared badly. True, he now had personal freedom, but war prices and the "innumerable evils which prevailed in this age of confusion" made his sufferings acute and long. Eventually his lot improved, thanks to organized self-help, the repeal of the corn laws, and factory acts; but meanwhile he had been in the track of a social tornado, which had torn him from his old moorings and left him damaged in status and living standards.

Toynbee put the industrial revolution into the series of historical phases. Henceforth it was apparent that for any understanding of the nineteenth century one must take account of English economics as well as of French politics. The term became popular, and at least two recent writers have described post-war efforts toward rationalization and the changes resulting from the coming of electric power and new chemical processes as "the New Industrial Revolution" (Meakin) and "the Second Industrial Revolution" (Jevons). But economic historians use the phrase with increasing hesitation and many mental reservations. They dislike the suggestion that revolutions in any generally acceptable sense of that term happen in economic affairs. "Sudden catastrophic change is inconsistent with the slow gradual process of economic evolution," says Birnie; "On the vast stage of economic history no sudden shift of scene takes place," says Sée; while Lipson emerges from a study of the seventeenth and eighteenth centuries with the conclusion that there is "no hiatus in economic development, but always a constant tide of progress and change, in which the old is blended almost imperceptibly with the new."

The modern view springs from a fuller knowledge of the periods both before and after 1760 than was possible in Toynbee's day. It is now known that the revolution did not "break" on an almost unchanging world of small scale non-capitalistic units, that the speed of transformation was far from rapid, that the ground was not quickly captured and that a picture of the social and economic evils of the period from 1760 to 1850 is far from filling the whole canvas. In the first place, the notion of an "eve" is blurred, if not blotted out, when it is discovered that the revolution had in 1760 "been in preparation for two centuries" (Unwin); that large scale enterprise under capitalistic conditions existed from at least the sixteenth century; that the changes in technique were "the completion of tendencies

which had been significantly evident since Leonardo da Vinci" (Usher); and that the developments between 1760 and 1830 "did but carry further, though on a far greater scale and with far greater rapidity, changes which had been proceeding long before" (Ashley). In the second place, the changes in productive methods depended on far more than a handful of inventions in Lancashire and Glasgow and with one or two exceptions took decades to work themselves out. The machines and engines raised as many problems as they solved—problems of metal supply, machine design, mechanical engineering, power transmission and so on. Machine production could improve only as quickly as did the production of machines and the invention of refinements to make their operation more efficient. The nature of some processes or materials was such that change was long delayed; wool combing refused to yield to machinery until about 1850, and wool yarn was so frail that even in 1860 the power loom in a woollen mill could work no more quickly than did the hand loom. In some industries change resulted from chemical discoveries rather than mechanical invention; in others, such as pottery, advance depended upon the discovery, by countless experiments, of new bodies, glazes, methods of decoration, better understanding and control of kiln temperatures as well as upon easier access by road and canal to raw materials and markets. Mining had no revolution; its story was one of "better methods, . . . slowly forged from the painful experience of common men, and only gradually did a new idea or a new device spread from pit to pit or from one coalfield to another" (Ashton). Building, one of the biggest fields of employment, suffered no revolution in methods until cheap steel and concrete were available. Thus with the one exception of spinning and its preliminary processes there was no sudden breaking of old methods or organization by "mighty blows." Professor Clapham's survey of British industry between 1820 and 1850 is a study in slow motion. He finds that "no single British industry had passed through a complete technical revolution before 1830" and reminds us that while the revolution had cut deep into the cotton industry by that date the Lancashire cotton operative was not the representative workman of the day. Even the typical town operative was "very far indeed from being a person who performed for a self-made employer, in steaming air, with the aid of recently devised mechanism, operations which would have made his grand-

father gape." Thus it is not until well into the nineteenth century that one finds the economic transformation approaching a stage that can be described as complete. A revolution which continued for 150 years and had been in preparation for at least another 150 years may well seem to need a new label.

Yet despite all hesitation the term stands and no better one has been devised. For there is in the period which began about 1750 something different in tempo and temper from that of any earlier epoch. The long inventive effort comes to a head in increased productive power, capital increases its power and resourcefulness, economic freedom is gained, domestic and foreign trade expand, the nature of the soil begins to be understood, goods can be moved more rapidly in greater bulk at lower cost for longer distances, and there is at least a "partial introduction of the methods of exact science in economic affairs" (Clapham). Any one of these things would have made a deep mark on the economic life of Europe; but when they came contemporaneously they interacted on one another and produced results which were far reaching and fundamental. From this "unprecedented social and economic development" (Unwin) the material appearance of England was changed "more profoundly than at any other time since the epoch of the last geological changes" (Tawney).

The familiar question, "Why did the changes come when and where they did?" is now best answered if the changes are regarded as the outcome of developments which had been under way since at least 1600. Those developments included a great expansion in the volume of domestic, colonial and foreign trade; an improvement in commercial and financial structure; some growth of large scale organization and production; some advances in industrial equipment; and some scientific discoveries capable of industrial application. British trade grew fitfully but substantially during the seventeenth and eighteenth centuries: the European demand expanded; the American colonists provided a growing market for textiles and hardware; the door into the Spanish possessions was forced wider open; while Africa, the West Indies and the Orient provided good markets and profitable materials for carriage to Europe. Such statistics as exist show that exports from Great Britain doubled between 1720 and 1760 and again by 1795. Meanwhile the British population grew rapidly after, at latest, 1730, thanks chiefly to a declining death rate. It lived on the largest free

trade area in Europe; the wealth which flowed in from oversea trade gave its people a larger spending power and fund of capital; and some of the goods it imported stimulated natives to find ways of making these articles at home, e.g. cottons and pottery. The French story is somewhat similar. Export trade grew almost fivefold between 1715 and 1789 and was probably larger than that of Great Britain in the latter year. Shipowners and merchants flourished, and capital accumulated. Holland and Scandinavia also shared in the general trade expansion.

Economic organization improved during the seventeenth century. Banking and exchange facilities became more abundant and satisfactory, and joint stock companies were established for a large variety of purposes. Industries which served large or distant markets (textiles), which needed large sums of capital for equipment (mining, finishing trades), which worked on costly raw material (silk, precious metals) or which supplied customers who demanded long credit and were slow in paying their bills (London high class tailoring, coach building) were passing into the hands of large entrepreneurs. Sometimes these men were big industrialists who had risen from small beginnings; but often they were merchants who established control over the production of the wares they sold. The merchant had capital or knew where to get it; he could afford to buy raw materials in bulk; he knew the needs of the market and he could allow long credit. He therefore sometimes gave orders to independent master manufacturers instead of buying what was offered in the open market; he supplied working capital to the mines from which he obtained his coal; but in some industries he took control. He bought raw materials and put them out to be processed by domestic workers; he supplied patterns and specifications and possibly the tools and equipment as well; while the final processes whether of finishing or assembling might be done in his own workshop. Independent master manufacturers still existed, who worked aided by the members of their family, journeymen and apprentices and sold their wares in fairs or local markets; such men could be found in the urban handicrafts catering for purely local needs and in the woolen districts of Yorkshire. But in the great staple industries—especially textiles—of France, the Low Countries and England the merchant was gaining control and sometimes counted his dependents by the hundred or even the thousand. At times the economies of supervision, discipline

and time saving were realized by gathering many of these workers under one roof; while in mining, brewing, soap making, smelting, shipbuilding, tanning and the finishing trades large groups of men had to work together by reason of the very nature of their work or of the equipment they used. Sometimes these groups worked under full factory conditions at machinery driven by power. Polhem's factory set up in Sweden about 1700 was remarkable for its use of machinery, water power, division of labor and mass production methods.

The sixteenth and seventeenth centuries also witnessed some advance in industrial equipment and scientific knowledge. Leonardo da Vinci's notebooks contain sketches of a spinning machine, a power loom, roller bearings, universal joints, gears, lathes, drills, rollers for shaping iron, coin presses, turbines, steam cannon and other things, but no one can tell how far they depict contemporary equipment or are the product of his fertile imagination. The stocking frame, invented about 1589, was said to contain over two thousand parts; and cloth finishing machines caused much controversy in the same century. Glassmaking, tinning, gold and silver refining, were all improved after 1600; makers of clocks, jewelry and instruments of precision obtained better equipment; a ribbon loom capable of weaving a dozen or more widths at once appeared in Danzig, then in Holland and finally in England; the Dutch developed the wind saw-mill and other devices for speedy production of ships; the French experimented with the "draw loom," by which patterned cloths could more easily be woven; Polhem's factory was full of power driven metal shears, slitting mills, rollers and hammers; and a silk throwing machine which had been known in Italy before 1300 was copied north of the Alps and reached England in 1718. The harnessing of water, wind and animal power became more efficient, as did the use of gears, while the use of treadles seems to have spread. The work of the growing body of scientists on atmospheric pressure had by 1700 laid a foundation on which the steam engine could be built. True, the seventeenth century saw more technical problems than it was able to solve but it was far from being devoid of inventive inquisitive minds.

The motives which led to the technical progress of the eighteenth century were many and varied. Steam engines and coke fuel came as aids to men who were fighting a losing battle. Shallow deposits of coal, tin and copper were being ex-

hausted, yet existing pumps could not cope with the water which seeped into the lower levels; ruin was inevitable unless the pumping problem could be solved. Ironmasters were faced with vanishing charcoal supplies as the forests near iron deposits were cut down; they must find a new fuel or abandon their furnaces. Many inventions aimed at saving labor, at making possible the use of children for processes formerly done by adults and at overcoming a scarcity of skilled labor. The whole textile industry was hampered in its growth by the fact that a large number of workers was needed to prepare yarn for one weaver; a cotton loom used the yarn made by four or five spinners; a woolen weaver kept nine or ten people busy; while in the sail-cloth industry Arthur Young found twenty yarn makers to each weaver. Since much of the spinning was done by country dwellers, weavers were often idle in summer when the spinners went to gather the harvest. In making patterned cloths the silk weaver needed the aid of three women to raise or lower the warp threads prior to the passage of the shuttle. In the metal industries the cutting of cogwheels for watches and other implements was slow and unsatisfactory until a machine was designed which "reduced the expense of workmanship to a trifle in comparison to what it was before and [brought] the work to such an exactness that no hand can imitate it" (Campbell). Watt, Roebuck and Wedgwood all had great difficulty in finding tools and men capable of making goods exact in measurement: there was an error of three eighths of an inch in a cylinder made for Watt. Wilkinson's boring machine was designed to make possible the production of cannon and cylinders which would be uniform in diameter.

Inventive ingenuity was also stimulated by the hope of monetary reward. Leonardo da Vinci had planned a needle polishing machine which was to bring him the income of a Medici, and eighteenth century opinion grew more tolerant toward the inventor's claim to compensation. Even when patent rights were challenged, it was agreed that the inventor should be rewarded by some gift from the state or from some organization set up to encourage invention. Kings and parliaments protected or rewarded innovators, and such bodies as the Society for the Encouragement of Arts, Manufactures, and Commerce, established in London in 1754, offered premiums, medals and prizes.

The spearheads of the technological advance in the eighteenth century were iron, cotton and

pottery, and it is no mere accident that this should be so. For these industries were virtually new to England and were free from vested interests and government control. More important still, they had two markets, one to be captured, the other to be created. They strove to capture existing demands which were already met by supplies from the continent or the Orient; but in addition they saw the vast demand which would spring into being if they could offer cheap cottons, crockery or iron. Wedgwood showed his grasp of the situation when he established a Useful Branch as well as an Ornamental Branch. In the latter he won a luxury market once served by Dutch, French, German and Oriental potters; in the former he created a new demand among all sections from the middle class to the poor. Lancashire cotton goods ousted oriental produce from the European, African and plantation markets and eventually invaded the Orient itself; they stole some ground from the linen and woollen producers; but the total was insignificant when compared with the new demand for more clothing and for domestic decoration which the cheap fabrics created. The story is not one of insistent demand compelling changes in productive methods; it is rather one in which changed methods and lower production costs resulted in a commodity which created a new big demand.

These many stimuli to industrial change were at work in both France and Britain all through the eighteenth century. In each country invention and imitation were active, and the search for new ideas was made abroad as well as at home. England had welcomed the Huguenots after 1685; Lombe had copied the silk machine from Italy in 1718 and become a big factory owner; London paper makers strove eagerly to learn the secret of French, Dutch and Italian superiority; London calico printers imitated the methods practised in Hamburg; while tin plate makers set up rolling mills of Swedish design. The English countryside was sprinkled with methods, rotations, crops and implements picked up by English gentlemen during their "grand tour"; and such publications as the *Annual Register* and the *Gentleman's Magazine* gave space to descriptions of industrial and agricultural innovations. If one dare talk of "the spirit of the Age," that spirit in the mid-century was certainly a powerful stimulant to interest in and search for new and better methods. Of that spirit nearly all sections of society were drinking.

Of the outcome of this enthusiasm no detailed account can be given here. The great inventors

and discoverers whose names are known often built on foundations laid by scores of obscure men; their work was frequently an improvement or refinement upon that of others and in turn needed still further improvement before it became really satisfactory. Crompton's mule was, as its name suggests, at least a crossbred and did not do its best work until it was made self-acting nearly fifty years later. Watt's engine was originally only an improvement on that designed by Newcomen sixty years before, and until it obtained a crank action was little more than a somewhat more economical pump than its predecessor. Some men went searching on wrong tracks, and their chief contribution was that of warning others not to seek solutions in those directions. Cartwright's loom, for instance, seems to have been almost worthless. In the gallery of inventors some canvases are too large, some should not be there at all and many deserving ones have not yet been painted, much less hung.

By 1789 it was becoming apparent on both sides of the English Channel that Britain was pulling ahead of its nearest rival in industrial and agricultural technique. Young boasted that France had no counterparts to Arkwright, Wedgwood, Darby, Wilkinson or Boulton and those Frenchmen who opposed the Anglo-French commercial treaty of 1786 pointed to the advantages Britain enjoyed through its lead in equipment; its comparative freedom from state interference; its supplies of iron, coal, china clay and water power; its access to raw materials; its abundant supplies of capital in London, Liverpool and Glasgow; and the power which its industrialists and merchants wielded in political life. These assets did much to make Britain the workshop of the world during the next fifty years; the Napoleonic wars strengthened its grip on the seas and weakened France's access to raw materials and markets, while the demands of these wars strengthened the demand for mass production of many commodities, a demand which the British inventions were particularly fitted to meet. Meanwhile France, which had been eagerly copying the British cotton and iron equipment before 1789, fell back; and although there was some development in the production of cotton, iron and sugar during the revolution and war it ended that period economically weaker, with foreign trade crippled, capital scarce, transport facilities disorganized and many skilled workers killed. Not until about 1830 did French economic effort begin seriously the task of modernization, and even in 1850 there was little that

deserved to be called an industrial revolution. Fuel and raw materials were insufficient; capital was scarce; facilities for industrial investment were scanty; and the Frenchman was wedded to individualism, agriculture and small scale enterprise. Alsace-Lorraine was lost before ways were found of turning its ore into steel. Hence nineteenth century France fell behind its traditional rival; Holland had no resources on which to build up the new kind of industry; and of the two countries which were best fitted to follow the English lead only Belgium moved quickly; Germany remained almost stationary until 1850, if not later. It had to wait until the Zollverein and railroads overcame the obstacles to easy movement of persons and goods. In Italy industrialization was retarded by political disunity and later by lack of raw materials.

Great Britain was therefore left almost alone in developing the new technique and organization. France did contribute something to the common stock of invention and discovery—silk throwing machines, the Jacquard loom, the tubular boiler, the water turbine, chemical bleaching, a sewing machine and other things. Germany gave attention to the relations between science and production; Justus von Liebig put agricultural chemistry on its feet in 1840; nearly a century before that date Margraaf had found there was sugar in beetroot; while in 1802 the Silesian Achard found a way of extracting it on a commercial scale and thus gave Europe a new industry. After 1800 the North American contribution began to be important, and by 1850 American machine tools and machine products were entering the European market. The keynote of the American development was mass production of standardized articles, each part of which was made by machinery designed for one task. Skilled labor was scarce; the frontier consumer wanted goods which were cheap, serviceable or labor saving rather than polished, well finished and long of life. The designing of special machines which could be attended and fed by unskilled workers therefore became the first manifestation of "Yankee ingenuity"; these machines produced parts which were of standard sizes and which could therefore be assembled quickly by the same kind of labor. From the making of muskets and revolvers this method of production spread to that of clocks, woodwork, sewing machines, harvesters, locks and the like. English observers in the 1850's marveled at the "fearless and masterly manner" in which "correct principles" were applied by American engi-

neers. Still the crucial developments which led to production by power driven machines did take place chiefly on British soil; it was there that the new factories, metallurgical plants, big coal mines, engineering shops, railroad and steamship were worked out and the resulting social problems had first to be faced.

The workshop of the world exported industrial products to all parts; but soon its customers wished to import industrialism instead, and the encouragement of that importation has figured largely in the politics of most countries. The motive of this state fostering of industrialization was the belief that it was derogatory, disgraceful and dangerous to remain a nation of farmers and handicraftsmen: dangerous because the handicrafts would be destroyed by the competition of imported machine products, because there would be no openings for those whose inclinations and talents were not rural and because the nation could not make its own war equipment; derogatory because the standards of the nineteenth century seemed to place the townsman on a higher plane than the rustic and the man who lived near a factory chimney above the hewer of wood, the shepherd or the cultivator; disgraceful because it was shameful to depend on other nations for the goods that one could and should make for oneself. If China, Japan and India were to count in the eyes of the western world they must westernize their industrial equipment as well as their judicial and educational systems; if Canada, Australia and even the United States were to emerge from colonial status or stature they must cut the ties that bound them to the factories of Lancashire, Yorkshire and the Black Country; if new or reborn nations, such as Germany or Italy, were to make their unity or freedom real they must translate nationalism into factories, mines, banks and statistics of industrial output; and if Russian communists wished to justify their faith and place in a hostile capitalistic world they must teach a nation of peasants how to make electricity, tractors, cloth, electric lamps and cheap matches. Hence the political thought of nearly every nation has been obsessed with problems of protection and self-sufficiency and of nurturing industrial growth in face of the competition of more highly industrialized countries. Only the crack of doom will end the debate concerning the extent to which success, where it has come, has been the result of governmental action in granting tariffs, bounties and the like or has sprung from such other causes as abundant natural

resources, improved transportation facilities, large home markets and the inventive ability, organizing capacity and industrious habits of the population.

In the New World there was some industrial revolution, but many industries came so late that they were able to begin operations on the modern plan. In the United States and to a slight degree in Australia and Canada there was some small scale and domestic industry to be destroyed or superseded. Colonial America had its frontier household manufacture of cloth, clothes, furniture and implements, its farmhouse processing of land and animal products, its charcoal smelting of bog iron, its nail shops, town handicraftsmen; distilleries, potash plants and shipyards. It had some putting out and some artisans who rambled round the countryside or worked in their own shops on materials belonging to their customers; and its flour, fulling or sawmills often treated customers' grain, cloth or lumber. But frontier conditions usually decided that the settler should rely on others only for those goods which he could not make for himself. Gradually most of these occupations passed into factories and workshops; there was a steady shedding of by-occupations by the farmer and a corresponding concentration on his main task. Improved roads, canals and finally the railroad brought a wider area within reach of factory products and spinning wheel, churn and candle mold became antiques. The interruption of Anglo-American relations during the revolution stimulated domestic production, while the period from 1807 to 1814 saw some adoption of machinery and factory organization; tariffs after 1815 helped the textile and iron industries over some of their difficulties with foreign competitors; the westward flow of population called for the production of settlers' effects at such inland points as Pittsburgh; the Erie Canal made it possible to process farm products at such centers as Buffalo and Rochester and to send them to eastern markets; the scarcity of labor stimulated the production of labor saving farm implements and industrial machinery; while engines had to be designed and built suitable to American railroad conditions. But agriculture and commerce remained the chief interests until the Civil War; capital and enterprise found their richest rewards in the unoccupied areas of the west, in the production of staples for the seaboard or the European market, in land speculation, in supplying the stream of settlers and in shipping. The really serious industrialization of the country did not

set in until after 1860; by that time the methods and organization which seemed most suitable had already been worked out in New or old England and only needed to be adapted when adopted. The extension of industrialization to the south of the United States, slowly since 1890, with increasing rapidity since 1914, has again involved the imposition of known industrial techniques on an agricultural economic organization. Australia and Canada had little of the old order to sweep away; their industries could begin on the modern pattern. The South American countries are still predominantly agricultural, the only important traces of industrialization being the penetration of modern methods of finance, large scale plantation organization and the spreading use of machinery in the extractive industries.

In the Near and Far East the machine technique has met a social organization far older and more stable than that which it superseded either in the countries of the New World or in Europe; but here too changes which may be called industrial revolutions have occurred or are in progress. The first of the oriental countries to feel the impact of industrialism was India. Conquest, railways and foreign goods introduced the system. The dissolution of the old princedoms and their courts, followed by the rapid introduction of improved methods of transportation, and the prohibition of the importation of Indian cottons and silks into England had gone far toward destroying the highly developed urban and village industries of India even before the products of English machines appeared upon the Indian market. Loss of older means of livelihood drove increasing numbers of artisans back upon agriculture, and meanwhile the relentless growth of population continued. By 1880 there were many observers who felt that the one solution of India's economic difficulties was the development of modern industries. The factory system appeared first in the 1850's with the building of cotton and jute mills. While the jute industry was developed almost entirely by English capital, the cotton mills were started by native Bombay merchants and the industry has remained largely in native hands. The growth of the cotton textile industry was slow until about 1880, when it began to expand rapidly. As has been true in most countries, machine spinning was at first far more important than weaving, large quantities of machine spun yarn being used by Indian hand loom weavers; even larger quantities were exported to China and for a time to Japan. This

Chinese market was eventually lost to Japan, and after the World War Japan became a formidable competitor in the Indian market itself. Until 1914 India depended entirely upon imports for her machinery and industrial equipment. Early attempts to establish an iron and steel industry failed; and though the stimulus of war demands caused a rapid development of that industry after 1914, it is still unable to supply the country's needs. The war led also to some development of chemical industries, oil and water power. India has today over a million factory workers, and the Calcutta jute mills are large scale units. But industrialism has touched scarcely more than the fringe of Indian life as yet; banking and finance are little developed, and the factory worker is often a villager who has come to town for a few weeks or months in order to earn money to supplement the inadequate income of the farm.

The same is true of China. Attempts at factory spinning of cotton were made as early as 1860 and were successful after 1880. These early mills were owned by Chinese masters, who gathered in their kinsfolk and thus retained something of the family unit. After China's defeat by Japan foreign capital was invested in cotton mills, and a large spinning industry—half Japanese, partly Chinese and slightly British—grew up in the Shanghai area. In that region about 250 factories now exist making textiles and a wide range of other consumer goods, including even fountain pens and gramophones; but elsewhere there has been little industrialization, except in Manchuria under Japanese influence.

The rapidity of the modernization of Japan seems to make the phrase industrial revolution particularly applicable in its case; but it is significant that the commercial and financial transformations have been more far reaching than the strictly industrial. Even before 1868 important changes in economic organization had been taking place in Japan; throughout the eighteenth and the early nineteenth century the feudal system was gradually being transformed by the development of a money economy, including a wage system. Under the modern government of the Meiji era industrialization became one of the first objectives of economic policy. Government subsidies secured by borrowings abroad made possible the construction of railroads and later of public utilities, gas and electric power works. The government established model factories and schools for the training of workers. Nevertheless, the progress of industrialization was slow;

not until after the Sino-Japanese and Russo-Japanese wars did Japan's factory industries develop on any large scale. The World War caused an enormous expansion of all industries and offered an opportunity for Japan to capture the markets of the Orient; but the troubled economic and political conditions of post-war years forced a considerable recession. In 1927 Japan had 49,000 factories employing 1,700,000 workers. The most important factory industries are silk reeling and cotton spinning; but the weaving of cotton is still preponderantly a domestic industry, while silk weaving is negligible. Raw silk remains Japan's principal export and the majority of the population is still agricultural or rural, engaging in handicraft industries as a subsidiary occupation. Japan is already experiencing difficulties in finding an outlet for its cotton yarns or textile goods in India or China, and the development of the heavy metallurgical industries is costly because of its lack of raw materials.

In one sense the vast changes in progress in Soviet Russia do not constitute an industrial revolution, since they do not represent the substitution of one form of industrial organization for another. But this industrialization of an agricultural country is in another sense completely revolutionary. It could occur of course only after the methods and instruments of industrialism had been fully worked out in other countries. The logic of large scale production, the factory system and the machine technique are being adopted more completely in Russia, through their extension to agriculture, than anywhere else. The pattern of industrialization, which has been much the same for most countries, is completely changed in Russia. The heavy industries are being developed first rather than last; industrialization, while depending on foreign aid and the exports necessary to pay for it, is not based on a foreign market for consumers' goods. The social consequences of the industrial revolution in Russia are also vastly different; great as the hardships involved may be they fall most heavily on such classes as the kulaks and the merchants, not on the factory worker. Russia possesses all the natural resources necessary for a most complete development of the machine industries; a labor force is in process of creation. It is easy to overestimate the rapidity of progress, but these changes do have a spectacular quality which the first industrial revolution never possessed even in retrospect.

In all lands where it came to displace an established industrial structure the industrial rev-

olution ran a roughly similar course. The textile industry was usually the first to be affected, then the making of clothes, metal articles and food-stuffs; the large scale manufacture of iron and of steel represented often a distinct step forward but one not easy to take, while the manufacture of machines and producers' goods generally was a hazardous venture. Indeed it is this final step toward complete industrialization which has been most difficult for more recently industrialized countries. In lands coming late to industrialism the easiest success has been won in industries which process the natural or farm products, which produce simple wares such as blankets or plain cotton pieces or which enjoy the natural protection of distance from possible competitors.

Migration of industry from manual domestic or shop conditions to the factory varied in speed from industry to industry. Spinning went quickly; weaving, knitting and some metal trades passed through a transitional workshop period, in which workers were gathered under one roof but continued to use the old equipment. In the clothing industries the sewing machine could be used in the home, and many women clung to the putting out system but had to submit to sweated conditions. The shoemaker and hand loom weaver put up a long fight, and the victory of the laundry and bakery is still far from complete in Europe.

Dependence on coal and water power led to industrial concentration on the coal fields, river valleys and such belts as the fall line in America. Water power had only a limited effect in causing concentration, for it strung the factories all along the banks of rapidly flowing rivers, and for certain textile washing processes an ample supply of water was almost as important as a supply of fuel or power. Where water and coal were found together, as in the Pennine valleys and eastern Belgium, industry was spread over the whole region in villages or towns. For the metal industries location was determined by the coal supply, since it was easier to bring the metal to the coal than vice versa; but this involved the construction of adequate transport facilities, such as the railroad between Lorraine and the Ruhr.

The movement of population to the industrial areas still needs further study. But for England it is now evident that there was no simple mass transfer of people from the south and east to the north and west. The industrial towns grew by drawing workers in from the hinterland, and the void thus made was filled by people from

slightly further afield. Journeys were generally short, except in the case of the Irish who swarmed across the Irish Sea to Lancashire, Glasgow and Yorkshire. Only later, when the railroads made longer journeys easier, was there any serious long distance migration. In newer countries, such as the United States, native population was for long streaming away from the eastern industrial centers and a continual inflow of immigrants was necessary to insure an adequate labor supply.

Problems of urban health and housing were probably most acute in those towns which were the homes of the early spinning factories. In looking at them it should be remembered that until 1835 many British manufacturing centers had no adequate municipal government, that knowledge about the essentials of public health was scanty, that cheap production of pipes, bricks and woodwork did not come until about 1840, that house building depended on the willingness of someone to sink capital in dwellings and that the rate of interest current or the profits to be made in industry might be more tempting than the return on house property. A glance at the housing of the poor in non-industrial towns of the eighteenth century and at the difficulties which have surrounded the provision of working class dwellings since 1914 should provoke a more merciful judgment of the "jerry builder" of the early nineteenth century. In the United States living conditions in the early textile towns of New England were very good; only with the coming of wave after wave of foreign laborers did the worst slum conditions appear.

Of labor conditions no easy generalization is possible. Long hours, child labor, employment of women, insanitary conditions, payment in truck, unemployment, low wages, capitalistic tyranny, labor unrest, industrial fatigue, occupational diseases and the "cash nexus" were not inventions of industrial factory capitalism. Night work was a new thing in the textile industries; but the only novelty about child labor was that children now worked in large groups, were subject to factory rather than parental discipline, discharged more responsible tasks, had to leave the hearth to work and were kept rigorously at their day or night tasks. It should be noted, however, that child labor was universally regarded as natural and that the children's earnings were larger in the factory than they had been at home. When child labor was forbidden, something else—education—had to be developed to fill the waking hours of the young. The

hazards to life and limb might perhaps have been prevented before they were attacked by legislation but they had first to be recognized as such, and the apathy toward them was as marked among the operatives as among employers. Such conditions and attitudes repeated themselves in most countries or regions where the factory system was introduced.

As to wages and employment light and shade alternate. In the early stages the new industries, especially cotton and pottery, seem to have paid much higher wages than were prevalent in the older industries, and the demand for hand loom weavers to cope with the flood of machine made yarn raised the rates paid for weaving. In England the long war with France lifted many nominal wages and some real ones, but the slump after Waterloo lowered levels in industry and agriculture alike. The hand loom weaver and some other manual workers suffered when they stuck to their benches in face of the machine; but elsewhere conditions seem to have improved because of rising wages and falling prices after about 1820 or 1830. Some occupations passed from male to female hands, but new occupations were opened up and old ones expanded—metallurgy, mechanical engineering, the construction and operation of railroads, shipbuilding, mining, building—and the opportunities for skilled well paid work multiplied accordingly.

In short, the industrial revolution increased rather than decreased the material welfare of the mass of the population; but some sections suffered from the transition, war and business fluctuations disturbed wages and prices and the dangers latent in the employee's lot became apparent. Unfortunately much of our view of the social aspects of the revolution is drawn from reports of official investigations, which in their very nature are full of complaints and grievances. From them one can paint the industrial revolution as "an orgy of soulless cupidity" (Tawney) and assume that to be the whole picture. But quantitative studies such as that by Clapham; detailed business studies of Oldknow, Owen, Wedgwood, Boulton, Gott, Krupp and others; and a more detailed knowledge of pre-revolutionary conditions tone down the picture and make at least some of the industrial leaders appear more like human beings and less like incarnations of ruthless self-interest. Moreover it is still far from certain how much the revolution was "a triumph of the spirit of enterprise" (Tawney). Enterprise there was but not always triumph, and the industrial field was strewn

with the wreckage of men who failed. The trouble with machinery that broke down, with workmen who refused to use it, with customers who demanded long credit yet refused to pay their debts, with booms that burst, with banks that refused any more loans, with wars that closed markets, all made the road stony. Inadequate supplies of working capital wrecked many a venture, and when a successful period came the profits had to be plowed back into the business. The industrial revolution has not yet been studied through the records of bankruptcy, but enough is known to show on what a treacherous sea the entrepreneur of the early machine age launched his boat.

INDUSTRIAL UNIONISM. See TRADE UNIONS.

INDUSTRIAL WORKERS OF THE WORLD. The Industrial Workers of the World, a revolutionary industrial union, was organized in 1905; its object is to organize the working class industrially not only for the everyday struggles against employers but for the final overthrow of capitalism. It was originally a socialist organization but since 1908 it has combined the indigenous American doctrine of industrial unionism with the ideology and practises of syndicalism.

The emergence of the I. W. W. was the result of the convergence of two forces: the frustration in the east of the socialists who wished to commit the American Federation of Labor and the Knights of Labor to socialist programs and the sharp differences beyond the Mississippi between the socialist Western Federation of Miners and the conservative, opportunist American Federation of Labor. In the early nineties Daniel De Leon and his followers in the Socialist Labor party were aggressively working in the east to convert to socialism the two chief national labor bodies of the country—the declining Knights of Labor and their vigorous competitor the A. F. of L. These efforts failed and the De Leonites, insisting that the conservative unions hampered the emancipation of labor, organized in 1895 the Socialist Trade and Labor Alliance, which was avowedly socialist and revolutionary. The alliance created considerable agitation but was not a success; dissatisfaction with these manoeuvres of the De Leonites, which were linked up with fundamental differences involving revolutionary and opportunist conceptions of socialism, led the opportunist faction to bolt the Socialist Labor party and at the turn of the century to set up the Socialist party, which opposed organization of dual unions and advocated "boring from within" the A. F. of L. Soon after its organization in 1893 the Western Federation had affiliated with the A. F. of L. but broke away in 1897; it waged ten great strikes during the period 1893 to 1903. In 1898, three years after the launching of the alliance, the Western Federation set up the Western Labor Union (after 1902 the American Labor Union), of which the federation itself

was the chief constituent. The American Labor Union was an industrial union, class conscious and strongly socialist; it proposed industrial unionism and independent political action "of all wage workers" as "the only method" of working class emancipation—in essentials the program subsequently adopted by the I. W. W.

By 1904 both the alliance and the American Labor Union were extremely weak—the one a purely propagandist body, the other important only as the expression of the Western Federation of Miners. Meanwhile new and aggressive labor struggles provided an opportunity for the agitation of revolutionary unionism. The defeat of the steel workers' strike in 1901 glaringly revealed the limitations of craft unionism; the victory of the coal miners one year later stirred labor everywhere. There was an increasing discussion of the need for a new labor organization, as the result of which a constitutional convention met in 1905 and organized the Industrial Workers of the World. The most important organization represented in the convention was the Western Federation of Miners; other organizations were the alliance, the American Labor Union, the United Metal Workers' Industrial Union and a few disaffected locals of the A. F. of L. There were also a number of individual delegates from both the Socialist Labor party and the Socialist party. The proceedings were dominated by De Leon, William D. Haywood, Eugene V. Debs, William E. Trautmann and Vincent St. John.

The I. W. W. arose primarily out of dissatisfaction with the craft unionism and conservative policies of the A. F. of L. The latter had repudiated the Knights of Labor policy of organizing all the workers, skilled and unskilled; its constituent unions were composed overwhelmingly of skilled workers among whom craftsmanship was still an important factor, and these unions refused to organize the unskilled workers (e.g. in the iron and steel industry). The I. W. W. on the contrary proposed to organize all wage workers, regardless of craft distinctions; it proposed moreover to organize them into industrial unions which would embrace all the workers in a particular plant, enterprise and industry. The I. W. W. thesis was: machinery is rapidly eliminating the craftsman's skill; the unskilled workers are becoming preponderant and it is necessary to organize them; without the organization of these workers into industrial unions, an integrated unionism paralleling the integrated structure of modern industry, it is impossible to wage effec-

tive war on the great combinations of capital. The craft structure of the A. F. of L., insisted the I. W. W., is not only incapable of organizing all the workers but develops the conservative policy of defense of exclusive craft interests (frequently at the expense of the unorganized workers) instead of the revolutionary policy of the overthrow of capitalism.

Although the I. W. W., including its predecessor the American Labor Union, was strongly influenced by the traditions of earlier experiments in radical unionism, it made important departures. The I. W. W. accepted the Knights of Labor idea of organizing all workers including the unskilled but it repudiated the K. of L. leaders' middle class ideology and adopted a definitely socialist policy. The I. W. W. agreed with the Socialist Trade and Labor Alliance that unions should organize for the overthrow of capitalism, but it substituted industrial unionism for the craft unionism of the alliance. This industrial unionism was an essentially indigenous product and constitutes an American contribution to revolutionary labor theory and practise; it grew primarily out of the rapidly increasing concentration of American industry. This concentration, in socialist theory, represented the socialization of production upon which socialization of industry and socialism depend; the I. W. W. accepted that conclusion but added a new concept—the industrial unions, paralleling the integration of industry, would become the basis of the future socialist society (whence the theory of "forming the structure of the new society within the shell of the old"). This conception was given its most brilliant formulation by De Leon, who considered it the fulfilment of Engels' theory that the government of socialist society would be an "administration of things"; Lenin accepted the conception as an adumbration of the Soviet system and as the ultimate form of government in communist society.

Within one year a split took place in the I. W. W., which led to the secession of the Western Federation of Miners, depriving the new organization of nearly one half of its 60,000 members. The split involved issues of revolutionary or moderate tactics and left control in the hands of the more revolutionary elements under De Leon, Trautmann, St. John and Haywood.

The secession did not, however, end internal controversy; a new struggle developed between the advocates and opponents of political action. Although in theory the I. W. W. was a product

of modern concentrated industry it drew its strength from casual labor in the west and immigrant workers in the east, men who by the nature of their work and social position had no stake in voting and who developed an antistate complex. This complex was emphasized by the frontier traditions of "direct action" which influenced western workers. In consequence a strong antipolitical tendency developed, aggravated by the struggle for party influence within the I. W. W. between representatives of the Socialist Labor party and the Socialist party. De Leon opposed the antipolitical tendency, emphasizing the Marxist conclusion that "every class struggle is a political struggle." The controversy over political action came to a head at the 1908 convention. The De Leon delegates were expelled and thereupon set up a rival I. W. W. with headquarters in Detroit, but it was never more than a propagandist group. It declined with the general decline of the Socialist Labor party, changed its name in 1915 to the Workers' International Industrial Union and struggled on to formal dissolution in 1925. The majority I. W. W., sometimes called the anarcho-syndicalist group, espoused revolutionary industrial unionism without affiliation or cooperation with any political party. The antipolitical bias of the groups now dominant in the I. W. W. was reenforced by syndicalist theory. But there were important differences between syndicalism and the I. W. W. The I. W. W. was an industrial union, while the European syndicalist groups were essentially craft organizations; moreover, where syndicalism envisaged the future society in terms of autonomous, loosely federated producers' groups, the I. W. W. proposed a more integrated economic organization of society and more highly centralized social control—the fundamental difference between the anarchist and the socialist conceptions.

In the midst of controversy and secession the I. W. W. was becoming a militant expression of class war in the United States. It made its appeal to all wage workers regardless of occupation, creed, color or sex, attempting to link up the immediate struggle with the necessity for the overthrow of capitalism. It opposed the intervention of intermediate agencies, such as the state, in labor's struggles with the employers and emphasized direct action in the form of strikes, boycotts and so on but not collective bargaining, which it considered an interference with labor's only weapon, the strike. Unlike the A. F. of L., which considered time agreements necessary

and sacred, the I. W. W. rejected them because such contracts make it more difficult to declare strikes at moments most embarrassing to the employers. The I. W. W. avoided violence and sabotage in spite of the emphasis on direct action; it talked much of those tactics but did almost nothing to apply them. Its tactics included intermittent strikes and strikes "on the job." In the course of its history the I. W. W. directed or participated in not fewer than 150 strikes, the most important of which were the Goldfield, Nevada, miners' strike of 1906-07; the Lawrence, Massachusetts, textile workers' strike of 1912; a lumber workers' strike in Louisiana in the same year, in which many Negro workers participated; the Paterson, New Jersey, silk workers' strike of 1913; and the iron miners' strike on the Mesabi Range, Minnesota, in 1916. The period from 1905 to 1914 was one of rising prices and stationary real wages, of aggravated labor discontent; these conditions provided an opportunity for I. W. W. militancy, and its activities were considered a serious revolutionary threat. Most of the I. W. W. strikes were marked by severe repression on the part of the public authorities; and along with their strikes the I. W. W. waged numerous "free speech" fights when their attempts to organize were interfered with. Arrests and convictions were numerous. The strikes were marked by temporary accessions to the I. W. W. ranks, the frequent winning of some or all of their demands and, at the end, abandonment of the battlefield without any serious attempt to build up a stable organization. This defect in I. W. W. tactics was aggravated by the difficulty of organizing unskilled workers, particularly when they were foreign born and spoke many languages.

During the World War the I. W. W. took an antimilitarist position, opposed the participation of the United States in the war and continued to organize strikes in spite of the truce proclaimed by the A. F. of L. The government acted swiftly and drastically; 166 of the I. W. W. leaders were indicted, 113 arraigned and tried and 93, including Haywood, convicted; they all received severe sentences, twenty years' imprisonment in the case of the more important leaders. The post-war years were marked by further prosecutions of the I. W. W. under the criminal syndicalism statutes of various states. In Washington agitation and strikes among the lumber workers aroused considerable tension; on Armistice Day, 1919, a group of American Legion men in Centralia attacked the I. W. W. hall

and met forcible resistance. In the struggle four legionaires were killed and a number of I. W. W.'s arrested; seven were sent to prison for from twenty-five to forty years; and although seven jurymen have since repudiated their verdict and there is a general demand for their release, the I. W. W.'s are still in prison. Wholesale prosecutions effectively broke the strength of the organization for a period of years—perhaps permanently. They forced it to concentrate what strength it had upon legal defense and campaigns for amnesty. Its energy was further sapped by bitter internal controversy over the conditions on which its members should accept amnesty. The I. W. W. played no part in the great strike movement during the period 1919 to 1922.

This decline was sharpened by I. W. W. losses to the communists. The communist revolution in Russia profoundly influenced the I. W. W., some of whose former members were active in the Bolshevik party. At first the I. W. W. was sympathetic to the Bolshevik Revolution; but as communist theory and practise with their emphasis on a political party and the capture of the state were better understood, a violent controversy over communism broke out. The controversy was aggravated by the organization of an American Communist party which struggled for hegemony over the revolutionary movement. An appeal issued in 1920 by Gregory Zinoviev in the name of the Communist International recognized the "long and heroic service of the I. W. W. in the class war" and urged it to join the International; the appeal said that the existing revolutionary situation did not permit of waiting until "the new society is built within the shell of the old," that the struggle of the workers must be a struggle for political power and that the I. W. W. theory of the general strike is incomplete unless it includes the final necessity of armed insurrection. The appeal was rejected; the I. W. W. emphasized its syndicalist orientation and became increasingly hostile to communism and the Soviet system. The Communists, however, were aided in the struggle by the fact that their program included fundamental elements of the I. W. W. program (as well as that of the Socialist Labor party); on the whole the I. W. W.'s have been Bolshevik and anti-syndicalist in their concepts of industrial unionism and the structure of the new society and syndicalist and anti-Bolshevik in their rejection of political action. The essential theoretical differences are: the I. W. W. believes in the gradual

acquisition of control of industry by economic action "on the job" and has no clear idea of how the final overthrow of capitalism is to be accomplished; the Communists accept industrial unionism but insist that it is necessary to overthrow the capitalist state and organize a dictatorship of the proletariat in order to build up the new society. These differences were at first a matter of discussion, and the Communists tried to win over the I. W. W.; in recent years the differences have become practical and have assumed the form of an open struggle for leadership over the revolutionary labor union movement. The Communist organization, the Trade Union Unity League, is opposed to the I. W. W. as well as the A. F. of L. In this struggle for leadership the I. W. W. has rapidly lost ground to the Communists. Left wing strikes which in pre-war days would have been led by the I. W. W. are now led by Communists. Many prominent I. W. W. leaders, such as Haywood and William Z. Foster, joined the Communist party, and an appreciable proportion of this party's membership is composed of former members of the I. W. W.

In 1924 the I. W. W. suffered a serious split over the question of centralization of power within the organization. Still smoldering differences regarding amnesty were also involved. The so-called Emergency Program, or E. P., faction, supported especially by western groups, favored the loose federation of highly autonomous locals. The eastern, or Administration, group favored continuance as an amalgamation of local units subordinated to a highly centralized national organization. The decentralizers were defeated but set up a Reorganized Faction with headquarters in Portland, Oregon, and formulated an emergency program calling for the abolition of certain national offices and the per capita tax to the general administration. In July, 1925, the E. P., or Reorganized Faction, adopted a new constitution which provided for the decentralization of the industrial divisions of the organization, called industrial unions, into job branches having local autonomy. Although this faction is still in existence it has even less influence than the dominant administration group. In Los Angeles it publishes a monthly paper, the *New Unionist*, which is extremely syndicalist in its theory and strike tactics.

The enrolled membership of the I. W. W. has never been large and has always been of a shifting, unstable character. The organization probably reached the peak of its popularity and

prestige at the time of the textile workers' strike in 1912, when it may have had 100,000 members. During the post-war period its membership and influence have been low and steadily declining. In 1930 it probably numbered less than 10,000 members.

Few skilled workers have been attracted by the I. W. W. Its strength has always lain in its effective appeal to the casual and migratory worker in particular and the unskilled worker in general. These groups, which the A. F. of L. has largely ignored and failed to reach, the I. W. W. has successfully recruited. Its more important branches are made up of such workers in lumbering, construction, agriculture, longshore work and marine transport. It has been strongest on the Pacific coast and in the wheat belt but has succeeded temporarily in the textile mills of Massachusetts and New Jersey, in the lumbering industry in Louisiana, in the coal mines of Colorado and in the oil fields of Oklahoma. Its chief centers of influence in 1930 were the wheat belt, the northwest woods and the docks of the chief port cities. It attracts most strongly the immigrants and the native Americans who drift into migratory work. Its leaders have for the most part been Americans, although some foreigners, especially Italians, have played active roles in its affairs. The activities and influence of the I. W. W. have been confined almost entirely to the United States and Canada, although there have been set up "foreign administrations," which simply reflect the propaganda activity of seagoing I. W. W.'s. The organization has no other international affiliation.

Of crucial significance is the practical result of the I. W. W.'s inability to combine effectively the struggle for immediate improvements with the struggle for final working class emancipation, a defect aggravated by its guerilla strike tactics and lack of organizational solidity. The result is that the I. W. W. has been far less successful as a disciplined labor union than as an organization of propaganda and protest. Unless immediate benefits can be offered—and won—workers do not stay in unions. This is why, although the I. W. W.'s have staged numerous strikes and free speech fights, these dramatic activities have borne little or no fruit so far as permanent, stabilized organization is concerned.

Although there have been among the I. W. W.'s not a few "two-card" men, holding union cards in some A. F. of L. union as well as in the I. W. W., the relations between the I. W. W.

and the federation have been for the most part bitterly hostile. The I. W. W. was conceived in hostility to the federation and since 1905 has been a most persistent critic of that organization and its policies. The federation, which is opposed to both syndicalism and communism, is highly conservative and represents primarily the interests of the skilled craftsman; the I. W. W. is radical and represents the unskilled worker, who is ignored by the A. F. of L. and whose interests demand more aggressive action. The two organizations typify sharply contrasted points of view—on doctrine, on tactics, on form of organization—as well as sharply contrasted groups of workers to whom they appeal. Many clashes have occurred between the I. W. W. and the A. F. of L.; the two organizations have denounced each other consistently and interfered in each other's strikes. During I. W. W. strikes the A. F. of L. unions of skilled workers would refuse to come out and were in consequence accused of "organized scabbery." These antagonisms are not simply a product of theoretical differences; they express the conflict of interests between the skilled and unskilled workers, the organized and unorganized, which constitutes an important aspect of the American labor movement.

The I. W. W. has been a significant influence in the American labor movement. Unquestionably it galvanized the A. F. of L. into taking more interest in the organization of unskilled labor; amalgamation proposals in the A. F. of L. are one result of the I. W. W. propaganda for industrial unionism. The industrial structure of some of the newer unions, like the Amalgamated Food Workers and several unions organized by Communists, such as the Needle Trades Industrial Union, is to be traced in part to the I. W. W.; indeed industrial unionism is an accepted idea of American communism. The I. W. W. has been responsible indirectly for state legislation more adequately to control private labor exchanges. It improved conditions among many groups of workers, especially in the lumber camps, and it has made it easier for Negro workers to organize into unions; in fact the I. W. W. was the first labor organization which actively organized the Negro. There is, finally, the influence of the I. W. W. upon the communist movement. The I. W. W. was an American expression of the revolt against moderate socialism which developed in all sections of the international socialist movement. In the pre-war days the I. W. W. stimulated the development

of a strong left wing group in the Socialist party; the struggle between revolutionary and opportunist was waged over the issue of industrial unionism. During the war the new left wing, which led directly to organization of the Communist party, was influenced, although in minor degree, by I. W. W.'s, while the Communist party now claims the revolutionary heritage of the I. W. W.

INDUSTRIALISM. Every age and every people has a character stamped upon it by the way it gets its bread. This is true not only of the modern era, which has been called the age of industrialism, but of all eras from the beginning of man's time on earth. It is as true of prehistoric peoples or of the ancient world as of modern Britain or the United States. Modern industrialism did not create man's dependence on his means of living or first cause society to take a shape governed by the nature of his economic

activities. It only sets a new shape in place of the old and causes societies to organize themselves in different ways.

Industrialism represents essentially a particular stage in human knowledge and in man's command over nature—a stage at which man has learned the arts of machine production and the use of mechanical power on a large scale but has not yet become so much the master of these new arts as to bring them to full maturity or under fully satisfactory control. It is a phase in material progress, but only a phase, destined to be superseded when its development has become sufficiently complete.

The point has not yet been reached when the world will have so thoroughly solved the problem of producing material wealth that it will cease to be a problem at all and men will be left free to turn their attention to the satisfaction of other needs and desires. Nor can one expect such a point to be reached over the world as a whole for a long time. Indeed in many countries poverty due to the underdevelopment of productive power is still by far the most pressing economic problem. The masses in China and India are still desperately poor, not from unemployment or misdirection of productive energy but from sheer inability to produce enough to provide a reasonable standard of living. Their great problem is still to increase production in order to raise their own power to consume.

But in the great industrial countries of Europe and America the situation is rather different. Not that enough is being produced to give all the citizens even of these countries a satisfactory standard of life—but in their case the further increase of actual production seems to be held back far less by a failure of productive power than by an inability to find means of distributing the increased real wealth which they are in a position to produce. Their problems are primarily unemployment, unremunerative prices, lack of proper balance between the output of different kinds of goods, dislocation of regular trading relationships between countries and a creaking of the financial mechanism by which the exchange of goods has to be carried on. They could produce far more with their existing resources than they are producing at present; but they cannot do this because there is something seriously wrong with their methods of distributing and exchanging wealth. And there seems little chance that their powers of production will be allowed to develop as they could until these fatal defects in the structure of indus-

trial society have been somehow remedied. Meanwhile production and the standard of life advance only by fits and starts; and progress is again and again interrupted by crises which cause the industrial nations deliberately to restrict their output of goods in an endeavor to create scarcity in place of a plenty which they have not learned to control.

How does such a situation arise? Obviously the power to create more real wealth ought to be the means to a higher standard of living for the community as a whole. Obviously on the whole and in the long run it has hitherto been so—witness the great advance in the real incomes of all classes in industrial countries during the past century. But it is no less obvious that this advance is less than it might be if the existing powers of production were being used to the full, and that even so it is made precarious by the liability of the economic system to recurrent crises and business depressions.

Industrialism is fundamentally an affair of productive technique. It is based upon the discovery and exploitation of improved methods of producing wealth, primarily in the processes of manufacture but also to an increasing extent in agriculture and in the extractive industries yielding primary products. It is closely associated with an increase in the scale of production, with the development of capitalistic methods in both manufacture and marketing and with the employment of wage labor. Its secondary effects have included hitherto a concentration of the population in densely inhabited urban areas, a very rapid increase in the volume of international trade, much lending of capital for development by the more advanced countries to those less advanced and a very rapid increase in the numbers and social importance of the middle classes, including those engaged in the professions as well as in the administration and supervision of industry and commerce.

At the basis of industrialism is the machine. Both capitalism and wage employment are much older than industrialism in the sense in which the term is used in this article; and there were many factories before there was a factory system based on mechanical power. But industrialism can be said to have begun when machinery driven by a central supply of mechanical power became the typical method of manufacturing production. For from that point industry replaced commerce as the directing force of economic life, and the scale of production and the forms of business organization came to be deter-

mined by the growth and character of mechanical power.

Thus in England, where the industrial revolution proceeded a stage ahead of its development elsewhere, the industrial employer step by step ousted the merchant from his previous predominance. The typical rich men of the seventeenth and the early eighteenth century were merchants and financiers engaged in buying and selling goods gathered together from a host of small scale producers. The few big employers who did exist were not typical. The rich clothier whose memory is kept alive by his monuments and benefactions in countless English churches was not primarily an employer of labor but a merchant, although the position of the small producers who supplied him with the goods he distributed may often have differed little in effect from that of wage workers. The bourgeois class to which the aristocrats of England and France before the great changes of the eighteenth century were compelled to pay some attention was above all a class of merchants.

The industrial revolution, based upon a great series of mechanical inventions and above all else on the economic utilization of steam power, radically changed the situation. It substituted for a relatively static system of production an essentially self-expanding technique. The merchant of the seventeenth or eighteenth century had indeed an incentive to expand his sales as a means to additional profits. But there was for him as a rule no economy in buying on a large scale or in larger total amount, since the small producers who supplied him could not produce more cheaply merely because they were asked to produce more. It is a commonplace among economists that handicraft production tends to obey a law of "constant cost" and indeed that, if additional workers have to be pressed rapidly into the service in order to meet an expansion of demand, costs will tend to increase on account of both the greater demand for labor and the less skill of the new labor attracted into the trade. This was undoubtedly the position in hand loom weaving in the eighteenth century, in the "golden age" of the hand loom weavers that preceded the introduction of the power loom. The desire of the eighteenth century merchant to purchase more goods from the small producers was therefore conditional on his ability to sell more without reducing the price or even while increasing it; and this, owing to the rapid expansion of trade with both America and the East, he was in fact often able to do.

But as fast as machine production based on mechanical power superseded handicraft, the situation was radically altered. Until then the pace of production had been set by the orders of the merchants, to whom the producers were for the most part merely subservient. But now under the new factory system the industrial employer himself had not only an incentive to get as large orders as he could but also a means of stimulating the merchant's demand. For in most cases he could produce more cheaply by increasing his output; and he was therefore, unlike the handicraftsman, in a position to offer the merchant goods at lower prices if only the merchant would increase his purchases. This enabled the merchant in his turn to take new steps in stimulating demand by offering goods at lower prices to the consumer both at home and abroad, and the increased orders given by merchants under these conditions reacted upon industry. But the initiative in the new system passed more and more into the hands of the industrial employer, whose offers of more goods at lower prices became the driving force of material progress. From this point of view the coming of industrialism was in manufacturing industry the transition from a condition of constant to one of decreasing costs.

The industrial employer, who thus became the pivot of the new economic system, found himself urged on to new conquests by the pressure of the machine itself. He had to be abreast of his competitors in reducing prices; and this was a perpetual incentive to him both to increase his scale of production and to avail himself of the improved machines that were constantly being produced. There was doubtless, even when the industrial revolution was at its height, an optimum size for any given business beyond which it could not grow without loss of productive efficiency. But as the optimum was growing larger with very great rapidity, the great majority of businesses were probably well below it and racing to catch up. Accordingly machine technique gave the employer the greatest possible stimulus to increase his scale and quantity of production in order to cut his prices and thus enabled the merchant to take full advantage of the elasticity of demand, especially in overseas markets.

This last qualification is necessary because the strong competitive pressure on employers to reduce costs and prices, while it was a powerful stimulus to improved productive technique, reacted unfavorably upon the level of wages and

therefore upon the consuming power of the domestic market. The employer could cut his costs not only by improving the efficiency of production but also by reducing wages or taking a firm stand against their increase; and this course appealed strongly to the less efficient employers, who were threatened otherwise with extinction. Relatively few employers could be brought to believe in Robert Owen's doctrine of the economy of good wages and conditions; and perhaps relatively few were efficient enough to make it true in their own case. The rapidly falling costs of the new industrialism were based on low wages as well as on a rapidly improving technique of production.

There was a second and no less powerful reason why wages and consuming power in the home market remained low in the period following the advent of industrialism. The new employers under a constant necessity of improving their machinery and expanding their scale of production were avid for fresh supplies of capital which they could apply to these purposes. But capital was hard to find in the days before the recognition of limited liability and the working out of the modern solution of joint stock companies and corporations based on widely diffused and easily transferable shares. The employer was therefore compelled to expand his business out of his own resources as far as possible, living frugally himself and putting back his profits as capital. Under this pressure he was disposed to resist demands for increased wages as sheer waste, the devotion to useless expenditure of resources badly needed for the expansion of output.

It is true that money thus saved was spent on buildings and machinery. But the constructional trades, powerfully stimulated as they were by these new conditions, did not quickly respond to the new technique or pass over from handicraft conditions of constant cost to conditions of decreasing cost. Building remained and remains in part even today a handicraft industry in which prices tend to rise rather than fall with any quick expansion of demand. And machine making continued for a long time to be a highly skilled job, demanding the services of highly skilled craftsmen who were limited in number and incapable of being reorganized on a basis of mass production. Not until the methods of producing iron and steel and of forging and casting had been revolutionized in the latter half of the nineteenth century did the engineering trades become at all generally subject to the conditions

of decreasing cost which had come to prevail in the cotton trade more than fifty years earlier. Consequently spending on building and machinery did not expand production in the same degree as spending on consumers' goods, which were on the whole more easily mass produced. This helps to explain the intense concentration of the new industrialism on the development of exports and the constant search for new markets abroad.

Industrialism grew then at first chiefly in the textile trades, making Manchester the effective capital of the new industrial world. It was no accident that the economists who based their doctrines upon industrialism in this first phase came to be called the Manchester school or that their outstanding dogma was a supreme faith in *laissez faire*. For their own experience seemed plainly to demonstrate the self-expansive nature of the new industrial system, its capacity constantly to increase the supply of goods while lowering their cost, and the value of competition in weeding out the inefficient producers and compelling the survivors always to adopt the latest advances in technique on penalty of being left behind in the race. What could be better than a self-acting system which at once benefited the consumer by lowering prices, rewarded the efficient with the high profits of the pioneer and weeded out the inefficient who misused the resources of production? It was not clearly seen at this stage how far those results depended on the superior efficiency of Great Britain over other countries, of whose markets she was therefore able to take her pick, or how low wages must retard the growth of consuming power in the home market. These difficulties came later; and before they had been fully realized the character of industrialism had been greatly changed.

For in time the new technique was extended from industry to industry until it came to embrace the industries producing capital as well as consumers' goods. The development of railways played a dominant part in this transformation, not only because the railway enabled the interior of countries and continents to be opened up for economic exploitation but also because the demand for railway material gave an enormous stimulus to the metal trades and compelled them to devise and resort to mass production methods. The new steel making processes of Bessemer, Siemens, and Gilchrist and Thomas gave the metal using industries for the first time a reliable and durable raw material to which methods of standardized production could be applied and

thus made possible the development of large scale enterprise in the engineering and kindred trades as well as in the translation of shipbuilding from wood to metal. The same causes revolutionized the coal industry, greatly expanded already in the earlier phases of industrialism, and created a new and powerful grouping of "heavy industries" to balance the older textile trades. With the coming of these new forces the authority of Manchester began to wane; and industrialism, no longer so fully wedded to *laissez faire* and competition, entered on a new phase which led on before long to the growth of trusts and combines, the recrudescence of tariffs and in general to a renewed attempt at regulating just those processes of production and sale which the Manchester school held should be left severely alone.

The explanation of this difference is not hard to find. In the first phase of industrialism the maximum expansion of wealth could be secured by concentrating as far as possible on those forms of production which most clearly showed their obedience to a law of decreasing costs—in other words, primarily upon textiles. This could be done as long as there was adequate scope for the expansion of the sales of industrialized countries in markets where native producers were well behind in efficiency. But in time it became clear that this expansion could not continue unabated unless steps were taken to develop the complementary powers of production of these less industrialized countries so as to increase their supply of goods which they could give in exchange for the mass produced manufactures of industrialism. The railway was the great instrument of this development, opening up in the less industrialized countries vast new sources for the supply of raw materials and foodstuffs. Incidentally this expansion helped greatly to raise wages in the industrialized countries, both because it enabled export to go forward at a greater pace and because it secured an abundant supply of cheap foodstuffs. In the fourth quarter of the nineteenth century there was a rise in both money wages and the purchasing power of money with the result that a great stimulus was given to consumption in the home markets of the industrialized countries.

In building railways and in supplying railway material and later in the supply of machinery produced on a large scale the industrialized countries advanced to a new type of export trade vitally different from the old. The sale of cotton textiles or woolen goods was essentially a cash

transaction to be balanced at once by an equivalent purchase of goods. But the sale of railway material and other classes of capital goods could not be conducted on these terms, for the purchase price could be paid by the buyers only if and when the railway or the factory became productive. Payment for such exports had to await the economic development of the countries to which they were sent and had then to be made in the products which their use had caused to be created. Consequently this second phase of industrialism was marked by a great increase in the export of capital—that is, in the loan of capital in order to make possible the export of capital goods—from the industrialized to the less developed parts of the world. Great Britain especially exported huge masses of capital to all parts of the world and above all to its own dominions and India, to the United States and to the South American republics. Capital was exported also to the continent but was as a rule more speedily repaid and railways and factories built with British money were bought back by native investors.

It would be far beyond the scope of this essay to describe the reactions of this growth of foreign investment on world politics and international rivalries and on the development of economic imperialism; here only its effects on industrialism in a narrower sense can be considered. It made possible a very rapid growth of the industries producing capital goods and speeded up in them the development of an intensified technique of mass production. Whereas in the first half of the nineteenth century the typical instance of large scale production was a cotton mill, by its close the types of large scale enterprise were to be found above all in the heavy industries in the great steel making plants of Bethlehem or Middlesbrough, the great armament factories, the shipyards and the great coal mines already closely linked with steel. In the heavy industries there was already a growing tendency for combination to replace competition and for the size of the business unit far to transcend that of the single manufacturing plant.

Even before this period technical development had begun to influence business structure. As has been noted, the earlier industrialists were sorely hampered by shortage of capital. There was no investing public in the modern sense and broadly speaking no one could invest money in industrial development unless he either lent it to a business man on his personal security or became a partner in the business without the

protection of limited liability and therefore at the hazard of his entire fortune. The gradually extended recognition by law of joint stock organization and limited liability removed this difficulty and opened the door to industrial investment by all who had savings or resources to spare.

Joint stock and limited liability not only increased immensely the total resources available for business expansion but also removed the limits to the size of the capitalist concern. Before this the entrepreneur's difficulty had lain in gathering together enough capital to equip and run a plant large enough to take full advantage of the economies of large scale production. But now he was able not only to do this but readily to expand the scale of business organization so as to bring a number of separate plants under a unified control. While the scale of business organization was still expanding under the inherent necessities of improving industrial technique, it was now able not only to reach these limits but also to pass beyond them. Indeed, as the larger concerns were often at an advantage both in raising fresh resources in the capital market and in getting credit from bankers and others, to some extent a premium was put on a scale of business organization considerably larger than that made necessary by the technique of production itself. In the early days of the trust movement there was a marked tendency for the increase in the size of the business unit to be dictated by financial rather than technological considerations, and this tendency was strongly manifested again in the troubled years after the World War in the gigantic mergers and concerns organized by Hugo Stinnes in Germany and in the unwieldy aggregations of businesses gathered under one control by Vickers or Lord Leverhulme in Great Britain.

There was also, however, a new technological tendency leading toward an expansion of the business unit on a scale very much larger than that even of the largest single plant. Under the earlier conditions of industrialism the plant was the essential technical unit and each plant could face its own technical problems independently of the rest. But the modern development of industrial technology is making the separate plants growingly interdependent in a variety of ways. In the first place, it is often essential, if the maximum economy in production is to be secured, to group together in very close relation and under unified control plants engaged in complementary industrial processes—in order,

for example, to save intermediate transport costs on bulky half finished goods or in order to utilize a waste product, such as blast furnace gas, in a subsequent manufacturing process. Secondly, it is often advantageous from the standpoint of economic production to reduce and simplify the varieties of a particular commodity placed on the market and for that purpose to secure at least as much unity of control as is necessary. Thirdly, the maximum economy is likely to be realized in many trades if each plant instead of producing a wide variety of goods in competition with the rest is in some degree specialized to the manufacture of a limited range of products and thus enabled to produce within this range upon a larger scale.

The first of these technological requirements leads to a growth of vertical combination; that is, the linking up of successive stages of production under a common control. The second leads to fairly loose horizontal agreements between firms at the same stage of manufacture but need not disturb the independence of each distinct business. The third leads to much closer horizontal integration, as it is found in such businesses as Imperial Chemical Industries, Ltd., or the English Steel Corporation, Ltd., or the Vereinigte Stahlwerke, A.-G., in Germany.

Karl Marx, whose analysis of the industrialism of the first half of the nineteenth century remains the most penetrating study of capitalist development, has often been arraigned as a false prophet because he predicted a growing concentration of capital and an increasing polarization of the two rival economic classes of capitalists and laborers. It is indeed the case that there is in modern industrialism no sign of the disappearance of the small employer and that the growth of joint stock organization has increased immensely the number of small part proprietors of capitalist business. But, on the other hand, the small employer has become increasingly an agent or subcontractor or a hanger on of large scale business; and the great body of shareholders in modern industry has literally no say at all in its conduct or control. There has been a tremendous concentration if not of the ownership at any rate of the control of capital. The old personal nexus between employer and worker has been snapped; and the real struggle for power today is to an ever increasing extent between the few controllers of large scale industry and finance and the organized force of the labor movement, with the middle classes and the small investors largely passive spectators of the

conflict. Even the growing body of industrial technicians, who should, one would suppose, occupy a key position in the modern world, have been able to assert themselves but little as an independent force. They have been in the main merely the executive servants of large scale capitalism, although in many cases their personal sympathies might range them rather on the side of labor.

It has been pointed out how industrialism in its first phase concerned itself mainly with the sale of cheap consumers' goods in the markets of the less developed countries and how in its second phase it supplemented this form of trade with the sale of capital goods fostered by the lending of capital and credit overseas. The second of these processes like the first cannot be expanded indefinitely without check. The first fails when it reaches the limits of the power of the less developed countries to offer more goods in exchange until their own productive resources have been more fully developed. This check leads on to the second phase; and this in turn fails when the burden of external debts upon the less developed countries becomes so large as to check further loans. Moreover as more and more countries pass under industrialism their rivalry in selling goods and lending capital to the less developed areas fills up the available markets more swiftly. The advanced countries find growing difficulty in selling their goods and lending their capital overseas on favorable terms. They scramble for openings and concessions; and, as Marx foresaw, international rivalries are intensified and cries of "overproduction" raised.

All this time the technological revolution knows no pause. It is always impelling industrialists to produce on a larger and larger scale and to create plants, based on heavier and heavier capital expenditure, which can be operated at a profit over and above the interest charges involved in their construction only if they are able to work full time and to find buyers constantly for their full output. Post-war Germany, for example, when it rationalized many of its industries with borrowed American capital, created a productive machine capable of producing very cheaply while it was fully employed, but only at high unit cost if the volume of output had to be cut down through a failure of markets. The same conditions apply to many types of business in the United States and Great Britain and in every advanced industrial country.

It is therefore plain that the technical conditions of modern industry imperatively demand

from the world of today an increase and a stabilization of consuming power. In default of this many of the greatest technical improvements are apt to mean not low costs but high because of the heavy expense of the capital equipment on which interest has to be paid. These high costs serve further to restrict demand both because they result in high prices, often artificially maintained, and because they throw potential consumers out of employment and so cut down their purchasing power.

But the increase of consuming power up to the expanding limits of productive capacity is a matter that industrialism under present conditions finds very hard to arrange. Herein lies the chief importance for the world of the gigantic experiment in socialist industrialism that is now proceeding in Soviet Russia. The Russians have set themselves not only to bring their industries up to the very last point of modern technological development—largely with the aid of American engineers—but also to industrialize in their vast country with its millions of peasant proprietors the technique of agricultural production. The socialized factories of Russia are of far less potential significance for the future of the world than its socialized farms.

But the importance of the Russian experiment does not lie mainly in the mere fact that the Russians are forcing on industrialization at a hitherto unprecedented pace but rather in the fact that they are doing this under conditions which insure an outlet in consumption for everything that they are able to produce. With the entire control of production and distribution centralized those in control are able to order what things shall be produced and in what relative quantities and also to distribute enough purchasing power among consumers to insure a sale for all that can be produced. All this of course can be done only within certain margins of error and subject to the export of enough goods to pay for what must be imported. But with the export trade in the hands of the state exports are not restricted to those that can be sold at a money profit. Foreign trade is in essence barter, and the state can put on imports prices calculated to represent the value of the exports needed to pay for them. Under these conditions Russia appears to be immune from the fears of overproduction or underconsumption which beset the rest of the industrial world. To whatever other objections its economic system may be open, it seems to have solved the problem of balancing production and consumption and thus

have set itself free to make the fullest use of every technical improvement in the arts of production.

This example of Russia raises a fundamental issue. How far are industrialism and capitalism the same thing viewed from two different aspects? Or how far are they two different and separate things connected only at a particular stage of the world's evolution? Historically the connection is close, but they can by no means be identified. For, as has been pointed out, capitalism existed long before industrialism and took at first a mercantile rather than an industrial form. It is arguable that as capitalism preceded industrialism and was modified by its coming so industrialism is destined to outlive capitalism, taking on a new shape, as in Russia, under socialist control.

For manifestly socialism, the child of industrialism, will not speedily take up arms against its parent. Industrialism bred socialism because it required the concentration of the workers into factories, their subjection to a common discipline of monotonous labor and an opposition between their demand for higher wages and the demand of the owners of the instruments of production for interest and profits. But socialism is not hostile to industrialism; basing itself on the demand for a higher standard of life for all, it therefore cannot afford to dispense with the fullest possible use of every technical device which will serve to increase production and lighten the burden of labor. It is true that the workers today may sometimes oppose the introduction of labor saving devices or other instruments of higher production through fear of unemployment or out of hostility to the capitalist controllers of industry. But if under a socialist system they get the instruments of production into their own hands, as they have done in Russia, they are bound to be on the side of changes designed to increase output or to lighten labor. Possibly at a later stage of the world's history, when the problem of producing enough to afford to all a satisfactory standard of material living has been fully solved, the mass of the people may declare against industrialism and express in deeds its preference for some other system; but assuredly that time is not yet. The advent of socialism would intensify and not retard the progress of industrialization.

This remains true despite the common indictment of industrialism that it condemns the great mass of the workers to a life of dull, monotonous and even irksome toil. It is easy to contrast the

skilled, varied and interesting labor of the handicraftsman with the deadening monotony of purely repetitive machine minding. But before industrialism arose what part of the whole population consisted of skilled handicraftsmen? Was it ever as large proportionately as the number of persons, including those in supervisory and professional work, to whom the modern economic system affords interesting and colorful employment? If the modern machine minder is to be contrasted with the guildsman of the Middle Ages, he should be contrasted with the mediaeval peasant as well. And if one is to stress the effects of machinery in destroying craftsmanship, it should not be forgotten what effects it has had—and the far greater effects it might have under proper control—in eliminating hard, disagreeable, unskilled and brutalizing labor.

The modern world cannot yet afford to restrict its use of machinery, both because there is much drudgery still to be eliminated and because the growth of working class power means an ever more insistent demand for a high and rising standard of life. If therefore capitalism gives place to socialism, the first phase of socialism will be more intensely industrialist than capitalism has ever been, because for the first time the whole community will be pulling together toward higher production over the whole field of industry and agriculture as well as in the management of domestic affairs to remove the burden of the drudgery of housekeeping now laid on half the human race.

It does not follow that industrialism need in its later phases preserve certain of the features most prominently associated with it up to the present time. Urbanization is still proceeding unchecked in the industrial countries, but its causes are now social quite as much as economic. The development of cheap road transport and of widely diffused electrical power is removing the technological reasons for close urban concentration of industry and preparing the way for a rediffusion which will enable it to be carried on under far healthier conditions. Little advantage has yet been taken of these opportunities, because no less essential to business than accessible power and cheap transport is an available supply of labor with sufficient housing and kindred accommodation. The business that wants to set up in the country has to attract its labor and often to house it and help provide it with the amenities of life. It cannot readily take on fresh workers to meet a rush or discharge workers when times are bad for fear of losing them

altogether. Accordingly only businesses catering for a stable demand are able to move out of the towns, and even such businesses are often deterred by the difficulties and initial capital costs.

Nor is this the only factor. Urban life has for the worker many attractions: its cheap amusements, varied society, the hurry and bustle of life and a sense of nearness to the center of things. It increases his freedom to change his job and his independence of his employer, whose eye cannot always be on him out of working hours. Men and women leave the country for the town from preference as well as from necessity, and business tends to stay near the sources of labor supply.

But here again a socialist system might make a great difference. For with the power of coordinated planning of industry in its hands it would have also the power of town and regional planning. It would be able, as the Russians are endeavoring, to create new small towns in the country areas and to equip them with the means of a varied and satisfying life, as only a few capitalists here and there have tried to do with garden villages and the like. Even so the socialist state would not succeed in decentralizing and de-urbanizing industry if the preference of the great mass of men was for living close together in great towns; but at least the other obstacles in the way of decentralization could be removed.

If under a socialist system industrialism should be intensified in order to provide a higher standard of life, there would nevertheless arise also a keener demand for leisure. The necessity of reconciling these two demands would only increase the pressure to make the most productive use of labor, to push rationalization to the furthest possible point and to eliminate all preventible waste of human energy. Hours of labor would doubtless be reduced; but the tendency would be to put more labor into each hour and then to aim at reducing the burden of this labor by increased mechanization of processes. If mechanization were applied with the conscious object of making labor less hard and intense as well as more productive, a great deal that is barely attempted as yet could be readily accomplished. The demands for more leisure and for more production do limit each other in some degree, but they are by no means incompatible.

Industrialism then does not connote capitalism, although it is historically connected with it. The essence of industrialism lies in certain technical forms of productive activity which are capable of being directed to various economic

ends and by radically different forms of economic organization. It may be, as Marx insisted, that capitalism has played an indispensable historic role in the development of industrialism, because only under the control of the autocratic individual entrepreneur could the new technical forces have found free play. Certainly it needed a strong directing authority to break up and replace the mercantile capitalism of the pre-industrialist era, to destroy the domestic system of small scale production and concentrate the workers in factories and towns, to accumulate capital at the expense of the immediate standard of living and to force upon the state an attitude toward industry consistent with the free growth of the new powers of production. Certainly the state itself, based on the aristocratic power of the landed classes, was at the time of the technical revolution quite unfitted to assume this directing role; and certainly the working class was equally unfitted, for it learned cohesion and became a force only as a result of its experience of concentration and discipline under the new industrial system. Capitalism was therefore for the countries that led the way into industrialism an indispensable stage; but it does not follow that industrialism once created depends on the survival of capitalism for its effective operation.

Indeed, to use again a Marxian phrase, there are signs today that capitalism has become a fetter upon the limbs of the industrial giant, holding back industrial development and checking the increase of production for fear of glutting the market. For the capitalist system of productive organization is based essentially on the incentive of private profit. The capitalist entrepreneur will not and cannot go on producing goods unless he can make a profit by their sale. His market is therefore limited not by the needs of the consumers but by their willingness and ability to pay him a remunerative price. As the prices he can get tend to fall as the supply of goods on the market is increased, the entrepreneur is disposed to retaliate by restricting production in order to keep them up to a remunerative level. But this reacts on his costs, which tend to decrease with larger and to increase with smaller output. Everywhere in the world today frantic efforts are being made to hold stocks of goods off the market, to buy up "redundant" factories in order to close them down and to maintain prices by valorization schemes at the cost of limiting demand. These are surely signs of something amiss with the capitalist world.

Some say that all would be well if capitalists

would but abandon their attempts to control the market and go back to competition and *laissez faire*. But there is no chance of their doing this, because so many of the factors of production that they have to use are now under external control. The state limits their authority by legislation, and trade unions are too strong both economically and politically to allow wages to be governed by the mere higgling of the market. Moreover, even if all these obstacles could be removed, where could world capitalism hope to sell the vast mass of goods industrialism is capable of producing unless it were prepared to let wages rise to a point fully corresponding to the growth of productive capacity? And that would ruin the capitalists of any one country unless that country were isolated from the rest of the world or unless all other leading countries did the same.

A return to *laissez faire* is impossible. The concentration of capital needed for the full exploitation of modern productive resources is too great to be left uncontrolled by the state; for those who have this concentrated capital in their hands will assuredly control the state unless it controls them. The attempts of capitalist combines to control production and prices are apt to defeat themselves, creating artificial scarcity, depression and unemployment in place of the plenty which man's technical command over nature is making possible. Is not the truth then that partial controls set up by groups of entrepreneurs for the maintenance of profits will have to be gathered up into a wider unified control of industry based on maximum production balanced by an equivalent emission of consuming power? There is nothing in this idea inconsistent with the development of industrialism. On the contrary, it seems that industrialism has now reached a stage at which its fuller development requires above all else coherent planning and unified control from the standpoint of consumption as well as of productive technique.

INFANT MORTALITY. *See* CHILD, section on CHILD MORTALITY.

INFANTICIDE is the murder of a newborn child committed by the parents or with their consent—a practise that stands apart both as to its origin and its associations from the killing of another man's child, which is simple murder. In some cultures parents are allowed to decide whether the newborn child shall be reared; if their decision is positive they will not thereafter under normal circumstances kill it. Older children are sometimes killed in times of famine—such cases have been known in Europe during sieges—but far from being customary these acts have been regarded as a breach of the moral law. Likewise if a mother, like Medea, kills her children as an act of spite against her husband, her deed is regarded as a crime and is remembered with horror.

Judging from its wide distribution, infanticide is probably extremely ancient. Destruction of human progeny is universal whether in the form of infanticide, abortion or contraceptive measures. Infanticide is the most primitive, since prenatal destruction involves anatomical and physiological knowledge. Even with this knowledge abortion is hazardous and consequently has never been as prevalent as infanticide, except where the latter is treated as murder.

The primary cause of infanticide is the difficulty of obtaining sufficient food, whether because the population has reached a saturation point or because of some temporary shortage. Among peoples such as the Africans and South Sea islanders, who suckle their children for as long as two years, a child born before the preceding child is weaned is sometimes killed. In communities such as those of the Australian aborigines, where women are indispensable for the food supply, no discrimination in infanticide is made between the sexes. In Rome, Greece, Arabia, India and China women of the upper classes, relieved by the males of the harder tasks both as an effort to keep them young and as a sign of rank, became an economic burden; and consequently infanticide fell mainly on the females. The necessity of finding a dowry for daughters contributed to a selection of female children for infanticide in China and India. Ancestor cults of Greece, Rome, India and China, which could be transmitted only through the males, also resulted in the destruction of girl infants. When a sorcerer or astrologer was consulted before deciding the fate of the infant, it was usually killed if the omens were interpreted as indicating that it would bring ill luck or calamity—a motive for infanticide familiar in

myths, such as that of Oedipus. The Roman Twelve Tables forbade the rearing of deformed children; in Sparta the newborn child was submitted to the elders, who exposed deformed infants to death. Athens did not enforce such infanticide, but Plato and Aristotle advocated the practise. In ancient Greece exposure often proceeded from affection for the previous children, from a desire to procure for them a standard of living which numbers would have made impossible. Illegitimate birth, which has been a common cause of infanticide, has remained practically the only cause in modern Europe, where infanticide has declined with the spread of contraceptive.

The decision as to whether to rear or kill a child is usually made at birth, probably because the parents become attached to the child if it is allowed to live for some time. In some countries there is a ritual reason: as long as the child has not gone through some sacrament it is not accounted a full human being or a member of the tribe. In Athens the decision was made prior to the *amphidromia*, a ceremony at which the child was carried round the hearth and so associated with the cult of the ancestors. The Frisian father could destroy the child only before the child had taken food and by this act had entered into communion.

The usual method of infanticide is by suffocation, by choking or by drowning; the infant's blood is rarely shed. The child may be exposed to starve, to die of cold or to be eaten by dogs—sometimes for the purpose of insuring death but more frequently in order to give it every chance of being picked up and reared by a stranger. Foundling hospitals have been established in China and in modern Europe to provide for infants so exposed. Conflict between parental affection and necessity also betrays itself in the rationalizations offered for the practise, such as the one found among the Chinese that female children by being killed are given a chance to be reborn as males.

In China edicts have frequently been issued against infanticide. In Europe the church in 305 decreed excommunication for life as the punishment for women guilty of the double crime of adultery and consequent infanticide; this sentence was reduced in 314 to ten years, in 524 to seven. The Council of Toledo in 589 directed clerics and civil judges to unite in their efforts to prevent infanticide due to poverty, which proves that the Theodosian code, which prescribed death, had remained ineffective. Infan-

ticide is condemned in the Koran (xviii: 38). Modern English and Scottish laws treat infanticide as murder—English law defines infanticide as the killing of the child after the entire body is brought from the womb alive; Scottish law from the time the child has breathed, whether or not it is completely out of the womb. The crown has usually exercised its right of mercy when defendants have been found guilty of this charge. French law also treats infanticide as murder; in practise juries find extenuating circumstances and acquittals are common. The penalty for infanticide in the German code is from three years' penal servitude to death. The Italian code reduces the penalty from between eighteen and twenty years to between three and twelve if the child is killed before being entered in the civil register, not more than five days after birth.

Child sacrifice is distinct from infanticide, for it is not a family arrangement but a public function usually ordered by persons other than the parents; it bears equally on males and females, particularly on first born, instead of last born; it knows no age limit; and rather than being performed for the purpose of keeping down numbers it is often resorted to in order to insure further progeny.

INFECTIOUS DISEASES, CONTROL OF.

See COMMUNICABLE DISEASES, CONTROL OF.

INFLATION AND DEFLATION. Although employed earlier, the terms inflation and deflation did not come into general use until the World War. Only with the severe currency disturbances initiated at that time was anything approaching a technical sense applied to them; and even now the meaning which an economist associates with them is apt to vary in accordance with his general views regarding the money-credit-price mechanism.

Some use the terms inflation and deflation in connection with expansions and contractions of currency only; others, with a better knowledge of money and banking phenomena, expand them to include primarily credit movements; still others limit their application to currency and credit disturbances connected with price movements more or less general and violent. In contrast, many associate inflation and deflation above all with the movements of foreign exchange rates and consequently are inclined to ridicule the idea of a gold inflation, however great the accompanying credit, currency and price expansions. Finally, there is in the United States a small group who insist on basing the definitions largely on the liquidity of banking assets, inflation increasing as liquidity declines.

Perhaps the most generally accepted definition of inflation is that it is the issue of too much money; deflation is commonly taken to mean the opposite of inflation—the issue of less than the right amount of money. The question is thus raised as to the standards or norms, the deviation of the circulating medium from which is considered to be either inflation or deflation. One group vaguely measures the extent of inflation or deflation by the deviation of the circulating medium from "the legitimate needs of trade." Sometimes inflation is defined equally vaguely as the multiplication of money in relation to goods, sometimes as the increase in the volume of purchasing power in relation to the total volume of transactions. A few refine slightly their definitions so as to make inflation or deflation mean an increase or decrease in the circulating medium in relation to "the legitimate needs of trade" at some given price level. Most of those using the above definitions are proponents of the quantity theory or of some modification of it; hence such deviations are expected to lead to or to support changes in the price level. Whether or not price changes largely supported by changes in the velocity of circulation would be considered as inflation or deflation is generally not clear.

Some writers go even further and make price change the sole criterion of inflation or deflation. Cassel, who has given perhaps the best although a far from exact statement of this position, maintains: "If no scarcity in commodities exists . . . the rise in prices is to be accounted for as a result of the more plentiful supply of currency—in other words as a result of inflation. The general level of prices, on this hypothesis, is a measure of the extent of inflation. If a scarcity of commodities sets in, . . . the rise in prices is thereby intensified. But even this further rise in prices may be regarded as a result of a too plentiful supply of currency and consequently of inflation. . . . In both cases the essential point of inflation is a too plentiful supply of currency. In the former case we estimate this excess only from the standard which prevailed before; in the latter case we also take into consideration the excess in the supply of currency which arises through the former standard being retained even after the supply of commodities has diminished" (p. 61-62).

Keynes too makes price change the criterion of inflation or deflation; but he distinguishes between two types, which affect the economic equilibrium quite differently. Changes in the price of output as a whole, which measure the extent of inflation or deflation, may be reflected in changes either in the cost of production, per unit (or income per unit) or in profit per unit (profit being the difference between sales price and cost of production including the normal remuneration of entrepreneurs). A price change reflected in income inflation gives entrepreneurs no incentive to expand the scope of their operations, but a price change reflected in profit inflation leads them to attempt expansion and results in a tendency toward a boom. Thus a stable price level would not necessarily maintain business equilibrium. If as a result of marked improvements in technique and organization the cost of production per unit fell while prices were kept stable, profit would absorb the difference, at least temporarily, and business expansion might result. If, on the other hand, prices were kept stable in face of higher costs of production, entrepreneurs would suffer negative profits and business contraction might result.

An altogether different criterion of inflation is advanced by a small group of writers who tend to identify inflation with extension of bank credit on the basis of unliquid assets.

According to Laughlin, one of the leaders of this school, only price changes resulting from monetary factors are to be considered inflation or deflation, since price changes caused by a scarcity or abundance of goods are only the natural and desirable result of such a condition. Further no expansion of credit based on liquid goods can lead to a rise in prices, as the newly created credit is exactly counterbalanced by the goods on which it is based. It is only when credit is granted on assets which cannot be liquidated without loss to repay the loan at maturity that credit is depreciated in terms of goods and inflation exists. Robertson and others pointed out that this coining of even liquid goods into money may lead to rising prices as the resulting deposits circulate from hand to hand. It might be argued further that since the liquidity of assets is usually high in periods of rising prices and low in periods of falling prices, inflation of credit, as Laughlin uses the term, would be most conspicuous in a period of declining prices; inflation as generally understood is of course usually associated with rising prices.

The writers prefer to define inflation (none too exactly) as an increase in the general level of prices growing out of an increase in expenditures while goods available for purchase are not correspondingly increased in amount. Likewise deflation is defined as a decrease in the general level of prices growing out of a decrease in expenditures while goods available for purchase are not correspondingly decreased in amount. Unfortunately in the present state of knowledge the relative importance of different factors in price change cannot be ascertained. It cannot even be said that all price changes have the same significance; some may lead to economic disequilibrium while others may be necessary to maintain equilibrium. Keynes has attempted, although not yet entirely successfully, to distinguish these changes.

In the past, major instances of inflation seem always to have been associated with government finance. An increase in government expenditures even if unusually large does not of itself lead to inflation provided the government finances itself by taxation. Under such conditions the increased demand for goods and services on the part of the government is approximately counterbalanced by decreased means of purchase on the part of its citizens. A rise of prices is not, however, excluded: it is possible that citizens will secure additional credit to avoid too large a

reduction in their expenditures. Yet inflation initiated by governments with balanced budgets is rare. In a period of war, when military requirements necessitate huge and sudden increases in government expenditures, it has usually been found inexpedient on economic as well as on political grounds to raise more than a small portion of the newly needed revenues through taxation. In such cases resort may be had to loans from private investors or banks or even to the direct issue of government paper money.

If loans from private citizens are relied upon, the effect may or may not be inflationary, according to the conditions of the borrowing. If each individual who lends to the government curtails his own expenditures by an amount exactly equal to the sum lent, total expenditures will not thereby be increased. The chief result will be a redistribution of the demand for goods. Whether or not price indices change would depend upon the articles included in the index and the extent of individual price changes resulting from the redistribution of demand. In most instances, however, individuals do not decrease their expenditures by amounts equal to the sums lent to the government. The unwillingness suddenly to change spending habits, the need of expanding production to satisfy increased demand by the military, the possession of highly acceptable collateral in the form of government securities and the usual liberal discount policy at the banks lead government creditors to restore the funds at their disposal at least partially by borrowing from the banks on the basis of the purchased government securities. If these bank loans are not offset by decreased loans of other types, the result is a net addition to bank credit likely to be used to demand goods.

The World War finances of the United States government furnish an excellent example of this type of inflation. Individuals were encouraged to "borrow and buy" government securities. To the extent that banks loaned on these securities without reducing their other earning assets the effect was much the same as it would have been had they loaned the same amount directly to the government. Gold exports were forbidden except under special permit. Reserve requirements of member banks were lowered and all reserves were required to be held at the Federal Reserve Banks; thus most of the reserve money of the country was concentrated in the central banks and the basis of credit expansion was much enlarged. At the same time rediscount rates were

kept low and member banks were encouraged to borrow on government security collateral at a preferential rate of interest.

If a government decides to finance its operations either wholly or partially by an expansion of bank credit or by increased paper money issues or by both, the sums it must raise will depend partly on the volume of goods and services needed and partly on price movements. If the prices of the goods which it purchases move slightly or not at all, the government will be able to balance its budget with relatively smaller issues. If these prices rise in direct proportion to the increase in the circulating media, the new funds required to purchase the same physical volume of goods will increase correspondingly. If, however, as is frequently the case, prices increase faster than the circulating media, the treasury may find that every inflationary attempt to balance its budget tends to create a greater deficit.

Major instances of inflation show that although the movements of circulation and prices are in general in the same direction, wide fluctuations in one may occur with only retarded and disproportionate or even dissimilar changes in the other. Perhaps more surprising is the fact that during such inflations the movements of prices tend to be far more correlated with the movements of foreign exchange rates than with circulation. The relationship between prices, circulation and foreign exchanges may be illustrated by the history of the World War and post-war inflations in France and Germany.

Soon after the outbreak of the war the French government, unable to raise sufficient funds by taxation and private loans, was forced to make up the difference by borrowing from the Bank of France. Throughout the inflation period these loans increased almost continually and by large amounts as receipts from other sources became more and more inadequate. Commercial loans instead of falling off to balance the increase of treasury loans rose as the lag of production costs behind prices increased commercial profits. At the very beginning of the inflation the increase of circulation may conceivably have preceded the rise of prices, but soon thereafter prices began to rise earlier and faster; it was only in 1926 during the last stages of the inflation that circulation did not lag perceptibly. Although prices probably moved slightly ahead of foreign exchange rates from 1919 to 1923 and exchange rates slightly ahead of prices from 1923 to 1926 during much of the period they

moved approximately simultaneously, with a slight tendency for exchange to precede. The lag of circulation behind both prices and exchange rates led to an insistence on the part of the French that the increase in circulation did not cause the rise in prices but was itself caused by the price rise as the existing circulation became inadequate to meet the needs of government and industry. In fact the increase in government purchases led to increased business activity and to price rises and these in turn to currency expansion as fast as the government warrants were cashed into notes of the Bank of France.

The German war and post-war inflation paralleled in many respects that of France. Shortly after the outbreak of the war the Reichsbank was allowed to suspend specie payments and to substitute discounted treasury bills for commercial bills as non-cash cover for its notes. Although the government had borrowed large sums from the Reichsbank and the latter's notes had increased considerably, the extent of inflation at the end of the war was not greater than that in several other of the belligerent countries. In the post-war period, however, large reparations payments and other heavy expenses made impossible—politically if not economically—the balancing of the budget, thus necessitating heavy inflationary borrowing from the Reichsbank. Even more than in France the movements of prices seem to have preceded in time and exceeded in extent the movements of circulation. As a contributing factor to the price rise the velocity of circulation showed a great increase, especially in the period of most rapid inflation. Evidently people were attempting quickly to exchange their money for goods in order to escape further loss of purchasing power. Although as in France the correlation between their movements was high, during most of the period prices showed a noticeable lag behind foreign exchange rates. With this tendency of prices to follow exchange and to increase more rapidly than circulation the government was forced to borrow in progressively larger amounts in order to get needed supplies. From industry too came the insistence that there was a shortage of credit and money and that instead of causing the price rise the increased volume of notes was itself made necessary by previous price advances.

The fact that during inflations the rise of prices tends to exceed the increase in currency is directly connected with the increase in the velocities of circulation of all types of cur-

rency: people attempt to reduce to the minimum the amount of funds on hand in order to escape the loss due to depreciation. Another explanation suggested by the fairly steady lag of circulation behind prices is the fact that prices of goods purchased on credit or manufactured to order are recorded two or three months before currency is needed to close the transaction. In countries where deposit currency is used in all business transactions of any magnitude the lead of the general index of wholesale prices over the issue of banknotes and paper money for hand to hand circulation may correspond roughly to the lead of wholesale prices over retail prices and wages.

One explanation of the close relationship between prices and foreign exchange rates is offered by the purchasing power parity theory championed in recent years by Cassel. Since, according to him, a monetary unit as such, that is, apart from its value as a commodity, has no utility other than its power to command goods in exchange, the demand for currency of country A in exchange for currency of country B is simply an offer to exchange purchasing power in one of the countries for that in the other. Therefore the valuation of one currency in terms of the other will depend upon the relative purchasing power of the two currencies in their own countries. Following this line of reasoning Cassel contends that apart from slight fluctuations the exchange rate between the currencies of two countries will remain unaltered so long as no variations take place in the purchasing power of either currency and no obstacles are placed in the way of trade. Should inflation occur in country A and the purchasing power of its currency be consequently reduced, the value of currency A in country B will necessarily fall in like proportion. If at the same time currency B has undergone inflation, the valuation of currency A in terms of currency B will as a consequence rise in corresponding degree. Cassel arrives thus at the following rule: "When two currencies have undergone inflation, the normal rate of exchange will be equal to the old rate multiplied by the quotient of the degree of inflation in the one country and in the other" (p. 140). He recognized that underlying his rule is the assumption that the prices of articles for export move in the same degree as the general price index. If the prices of exports rise more than the general price index, the country's money will buy correspondingly less of the foreign currency; but if the prices of a country's

exports rise less than internal prices, its money will buy correspondingly more of the foreign currency.

This theory has been subjected to severe criticism on several points. Keynes states that it is only a truism to say that the relative value of two currencies can be derived by finding their relative purchasing power over goods entering into trade between the nations involved, but he would deny validity to the assertion that rates of exchange can be found by comparing comprehensive indices of internal purchasing power. The observed similarity between actual exchange rates and theoretical purchasing power parities arrived at by comparing wholesale price indices he would explain largely by the fact that those indices as at present constructed are dominated by articles enjoying an international market.

Nogaro points out that as goods purchased in international trade can often be produced at home only at prohibitive or very high costs, Cassel's contention that merchants will refuse to purchase a currency quoted above its purchasing power parity is too strict to be tenable. He prefers the older, less strict and in his opinion more nearly tenable theory that if foreign exchange rates rise faster than prices, exports will be encouraged and imports discouraged, thus tending to restore the balance of payments and to reduce the disparity between price and exchange movements. Further he denies the existence of a purchasing power parity, from which any deviation will set into operation influences tending to restore the norm. Internal prices are not fixed by factors independent of exchange rates. If foreign exchange rates rise faster than prices, the cost of imports in terms of home currency rises. At the same time the high price obtainable for bills of foreign exchange raises the price of exportable goods in the home market. Certain psychological effects may also ensue. Considering the rise in foreign exchange as evidence of probable future price increases, consumers may hasten to exchange their money for goods. Sellers instead of basing sales prices on actual cost or on cost of replacement may base them on prevailing or even expected future exchange rates—a practise common in Germany during the period of most rapid inflation. Thus a rise of exchange rates above the purchasing power parity resulting from exchange speculation or from any other factor in the balance of payments may serve to draw internal prices with it and thereby establish a new purchasing power parity. Nogaro also points out

that this tendency of internal prices to move with exchange rates prevents the automatic adjustment of the balance of payments which would result from the encouragement of exports and from the discouragement of imports and hence to that extent fails to stabilize exchange.

Of the evils of rapid inflation there can be little doubt. Although for some time the rise of selling prices above costs increases profits and stimulates production, when inflation becomes extremely rapid entrepreneurs often hesitate to enter into contracts drawn in money and production becomes deranged. Long term creditors find their claims virtually wiped out, and the amount of new capital offered for long term investment soon declines. The banks do a rushing business in extending short term loans despite the rise in interest rates. During progressive inflation, however, the rise of the market rate of interest compensates but slightly for the depreciation of the principal; business enterprises are thus not only largely relieved of their bonded indebtedness but are tendered a continuous subsidy by the banking system of the country. The victims of inflation are those whose money incomes do not rise as fast as prices; creditors, salaried workers and wage earners find their real incomes reduced as the monetary unit loses purchasing power.

The end of inflation is usually marked by credit stringency and numerous bankruptcies. The ensuing scramble for liquidity intensifies the liquidation of both business and banks, until in turn the volume of credit and prices are reduced far below their otherwise normal levels. Only by drastic measures, which are rarely applied except by accident, has the downward movement been speedily checked. With the decline of prices come decreased production and a shift in distribution. Recipients of fixed incomes, wage earners, salaried workers and creditors find that their money incomes have greater purchasing power than before. This gain may be more than balanced, however, by loss of employment and defaults in payments. Entrepreneurs and debtors, on the other hand, find their incomes greatly decreased and their obligations harder to pay.

While major inflations receive their impetus from treasury needs and are later fostered by business expansion, minor inflations commonly occur during the upswing of the business cycle. Although inflations characteristic of recurring periods of prosperity never attain the heights reached during inflations fostered by governments they follow a similar course. Some occur-

rence or group of occurrences leads to actual or prospective profits. Expansion of operations and of borrowing ensues, which gradually becomes more general and further increases profits. With new and increased loans made to profitable and expanding business a rise in prices is sure soon to follow. Inflation has thus made its appearance through normal business processes. As in the major cases, the end is frequently set by the limitation of credit either at home or abroad; liquidation and usually deflation ensue.

INGENIEROS, JOSÉ (1877-1925), Argentinian psychiatrist and sociologist. Ingenieros, who holds a commanding position in Latin American thought, elaborated the economic interpretation of history traditional in Argentina by ultimately explaining economic behavior in terms of biological processes. From this point of view he wrote on the living and working conditions of the proletariat and on the history and thought of Argentina. In his approach to the problems of psychology and philosophy he was

neopositivist. He condemned mediocrity but recognized the part played by the average man in preserving and transmitting the variations useful for the continuity of the social group. In criminology, which was his earliest sociological interest, he is best known for his classification of delinquents, which categorized criminals according to whether their delinquency was associated with the intellect, the feeling or the will. He was critical of the value of Spanish culture in South America, opposed Pan-Americanism as an instrument of imperialism and led a group which turned its intellectual sympathies from France to Soviet Russia. The Unión Latino-Americana, established in 1925, was a result of a campaign which he initiated. In addition to his many stimulating and widely read books in all fields of the social sciences he founded and edited the *Archivos de psiquiatría y criminología, medicina legal* (12 vols., Buenos Aires 1902-13) and the *Revista de filosofía* (1915-), which is still published.

INGERSOLL, ROBERT GREEN (1833-99), American lawyer and lecturer on agnosticism. Born at Dresden, New York, the son of a Congregational minister, Ingersoll spent his boyhood in small town parsonages in his native state and in Ohio and Illinois. He was admitted to the bar in 1854, entered Illinois local politics as a Democrat and saw brief service in the Civil War as

colonel of the Eleventh Illinois Cavalry (Volunteers). In 1863, having resigned from the army following his capture and parole, Ingersoll resumed the practise of law and joined the Republican party. He immediately attained fame as a lawyer and was especially noted for his ability in rapidly assimilating a brief and for his skill in gracious but devastating examination of witnesses. As leading counsel for the defendants in the notorious "Star Route" trials he performed one of the outstanding legal feats of the second half of the nineteenth century by securing their acquittal in 1883.

For a whole generation because of his great oratorical gifts and his enthusiastic acceptance of the tenets of Republicanism Ingersoll was one of the chief adornments of his party. At the nominating convention of 1876 his designation of Blaine as a "plumed knight" almost saved the day for his candidate. He campaigned for Garfield. His violent attacks on the leveling doctrines of Bryan in 1896, his defense of the war with Spain and his acceptance of McKinley's expansionist program put the stamp of approval, for many, on the newly developed capitalistic-imperialistic policies of the Republican party. Ingersoll might well have attained high public office had it not been for his radical religious beliefs; his conservative views on political and economic questions made his social acceptability assured.

It was as a foe of religious orthodoxy that Ingersoll was best known. For thirty years, using the lecture platform largely as his medium and talking before great assemblages, he expounded with great force and eloquence a simple agnostic creed the chief articles of which were a protest against the doctrine of eternal punishment, a denial of the certainty of the existence of God and a rejection of the inspired character of the Old Testament. These orations were singularly effective and succeeded in shaking the faith of thousands. Not an original scholar, he had an alert and absorptive mind and was familiar with the popular scientific writings of his day, particularly those of Huxley, and with the higher Biblical criticism. He selected as his own guiding principles those of "observation, reason and experience." On the other hand, he did not concern himself with the part played by organized religion in the support of dominant economic and political groups. Among Ingersoll's more notable lectures were "Some Mistakes of Moses," "The Gods," "The Ghosts," "Superstition," "The Truth," "Some Reasons Why,"

"The Foundations of Faith," "What Is Religion?" "The Liberty of Man, Woman and Child."

HARRY E. BARNES

Works: The Works of Robert G. Ingersoll, 12 vols. (New York 1900).

Consult: Kittredge, Herman E., Ingersoll: a Biographical Appreciation (New York 1911); Rogers, Cameron, *Colonel Bob Ingersoll* (New York 1927); Baker, Isaac Newton, *An Intimate View of Robert G. Ingersoll* (New York 1920); Smith, Edward Garstin, *The Life and Reminiscences of Robert G. Ingersoll* (New York 1904); Dibble, R. F., "The Devil's Advocate" in *American Mercury*, vol. iii (1924) 64-70.

INGRAM, JOHN KELLS (1823-1907), Irish scholar and sociologist. For the major part of his life Ingram was connected with Trinity College, Dublin, where he was successively scholar, fellow, professor of oratory and English literature, professor of Greek, librarian and senior fellow. He wrote on mathematical, statistical, philological and literary subjects and also published a volume of poems. But he is chiefly important as an economist and sociologist. After studying the writings of Comte he became at the age of twenty-eight a convinced positivist. His main works in this field are devoted to an exposition of positivist views on ethics and religion in their relation to society. They include *Outlines of the History of Religion* (London 1900), *Human Nature and Morals According to Auguste Comte* (London 1901), *Practical Morals* (London 1904), *The Final Transition* (London 1905) as well as *Passages from the Letters of Auguste Comte* (London 1901).

Ingram's conception of economics was largely determined by his positivist sympathies. He considered orthodox political economy—as represented, for example, by Cairnes—to be at fault in that it tried to study wealth in isolation from other social phenomena, was abstract and inhumane, deductive and unhistorical. In his view economics should be treated as merely a part of "sociology"—the empirical study of the evolution of social life and institutions in general. In opposition to the German historical school he held that such a study need not be confined to description; it could formulate laws, not indeed of static equilibrium but of changing development. This thesis he first enunciated in his address to the British Association in 1878, published the same year as *Present Position and Prospects of Political Economy* (London 1878). It is implied throughout his *History of Political Economy* (Edinburgh 1888, republished from

his article in the ninth edition of the *Encyclopædia Britannica*, vol. xix, 1885; new ed. with supplementary chapter by W. A. Scott and introduction by Richard T. Ely, London 1915), which constituted the first comprehensive and authoritative history of economic doctrine in English. These two works, although exaggerating the interdependence of the social sciences, were nevertheless influential along with the writings of Ingram's fellow countryman Cliffe Leslie in broadening the basis of economic studies throughout the world. In the United States they provided one of the chief sources of inspiration for Richard T. Ely and the "new school of economics." Ingram also wrote a *History of Slavery and Serfdom* (London 1895).

INHERITANCE is the entry of living persons into the possession of dead persons' property and exists in some form wherever the institution of private property is recognized as the basis of the social and economic system. But the actual forms of inheritance and the laws and customs governing it differ very greatly from country to country and from time to time. There is no "natural" law or principle of inheritance, which is essentially a changing thing, based on the changing forms of economic and social organization; for the special laws and customs governing inheritance are always and everywhere part and parcel of the general structure of property relationships. Changed ways of owning and using property will always bring with them in the long run alterations in the laws and practises relating to the inheritance of wealth.

Unless there is private property, owned or possessed by individuals, the question of inheritance hardly arises. For whereas an individual dies and his property, if he has any, has to be disposed of in one way or another, a group, such as a clan or tribe or family, does not die. Members die and are replaced by new members in the common enjoyment of the property of the group. The property itself, however, never changes hands or needs to be disposed of. Under such conditions there is no inheritance, in the sense in which the word is used in this article, because the group is conceived of as the

repository of the right of possession. This is one reason why inheritance plays a very small part in the life or laws of most primitive societies. The group holds in common and is tenacious of its rights. The individual does not hold but only shares in the use; and accordingly, when he dies, there is nothing for anyone else to inherit.

Even when there is in primitive societies individual property of a sort it can seldom be inherited. For where most property is group property, what is recognized as a man's own is usually limited to things so personal to himself that it would appear impious to hand them over to another at his death. His weapons, his simple tools and utensils are thought of as extensions of his own personality, as in modern times Hegel and other philosophers have thought of property over a far wider field. As part of his personality they are often to be burned or buried with him; and this tendency is the stronger because it is commonly believed that the dead will have need of them in another world. The deceased must take his means of creation and expression of his personality with him to the other world; and consequently no one else may inherit them in this. The very idea of inheritance in any shape or form is slow to develop in societies where private property scarcely exists.

But as fast as private property develops, and especially as soon as it touches the means of production beyond mere tools of a craftsman's trade, inheritance comes with it. Indeed property in the sense of ownership is not essential; it is enough that there should be private possession and use, for rights over things can be passed from the dead to the living as well as things themselves. There is a right to succeed to a tenancy as well as to the ownership of a farm; and many forms of inheritance are in effect successions to rights and sometimes to duties rather than to things. This is obviously true of hereditary titles and offices as well as of many forms of feudal and similar tenure. Indeed in one sense all inheritance is of rights or duties; and these rights and duties are only sometimes embodied in material things.

The inheritance laws and customs of societies are apt to be most complicated where they are still based, in part at least, on a lingering sense of group possession or ownership. Complete freedom to bequeath property or to give it away during a man's lifetime can develop only under social and economic conditions based on highly individualistic notions about property. A thing must be absolutely a man's own in a most indi-

vidual sense for him to have a full right to give or bequeath it to whom he will. Indeed only among English speaking peoples, where in general only dower or similar rights created by statute limit free disposal by the testator, does full freedom of bequest exist today or has it ever existed; and even in their case it is fairly modern, a product of an increasingly individualistic economic system. It does not exist in Scotland even now or wholly in the United States; and there is no continental country in Europe that even approaches it. Everywhere except in England and in countries which have borrowed their legal institutions largely from England property still retains something of a group character. It is not purely personal, and it has functions apart from the purposes of its possessor for the time.

This is most clearly seen in such institutions as the legitim, the legally enforceable claim of widows and children to at least a part of a dead husband's or father's estate. The legitim takes many different forms but it exists in some form and degree in the great majority of countries, including South American and important European states, exclusive of Russia, and Louisiana in the United States. Nor is it reasonable to regard it simply as a restriction on the right of bequest; for that would imply free disposal of property by will or gift to be the natural and obvious thing. It is so far from being natural or obvious, however, that it has never occurred to the great majority of mankind that it ought to be the main way of disposing of property. On the contrary, in all peasant countries there is still a strong tendency to think of real property at least as belonging to the family rather than the individual. It is the family's means of life, from which no member can be shut out except for positive misconduct. Property is no longer common to the family, as it used to be to the clan or tribe; but neither is it purely the personal property of the head of the family.

Naturally the notion of a group right or claim clings most tenaciously to forms of property which the group actually uses as instruments of production. The more property ceases to have this character and takes the form of money or shares in undertakings which are not purely family affairs, the less the group feeling remains attached to it. The family's claim to money or to shares in a joint stock concern is far less deeply rooted in tradition and seems far less compelling than its claim upon the family estate as a means of life. Townsmen in India often exist on pitances derived from the family land, which is

regarded as charged with the maintenance of all the members. Even where property takes a money form or that of paper claims on the earnings of businesses outside the family's control, the notion of the estate as a group possession usually dies hard. It is not dead even in England or the United States; there it asserts itself not only in the laws governing intestacy but also even more powerfully in social custom, influencing the wills men actually make, even when they have full legal freedom to make what wills they like.

Modern forms of economic organization are very powerful solvents of the group notion of property, for they tend to make the claims to income arising out of property divisible without the need for dividing the property itself. The chief argument against the legitim in most of its forms is that it tends to a more and more minute subdivision of property. Where landed property is the chief form of wealth, this may have very serious results not only in the breaking up of large estates but also in the subdivision of peasant holdings to a point which makes agricultural improvements impossible and reduces holdings to a size too small to admit of a tolerable standard of life. The institution of primogeniture has been upheld mainly on the ground that it keeps estates and agricultural holdings together, thereby making possible their more efficient development for the production of wealth. When, however, property comes to consist largely of stocks and shares, the arguments against division have far less force. In public companies and corporations the parceling out of the shares among a larger number of holders has little effect upon management; even in the case of family businesses charges can be made on the net earnings for different members of the family, and where such a business is turned, as now often occurs, into a private company, actual shares can be issued and the business still carried on without change of policy. It can be urged that the setting up of charges on the business or the diffusion of the ownership of shares makes the accumulation of capital out of reserved profits harder than it would be if the whole business were inherited by a single owner. But this is only one aspect of the wider argument that great inequalities of wealth and income are necessary for the adequate accumulation of capital in modern societies. In general there is no doubt that the institution of shareholding in joint stock concerns as the outstanding form of property ownership has made far

easier and less open to economic objection the diffusion of estates at their owners' deaths.

This diffusion tends to a more individualistic conception of property rights; for, save in the special case of businesses which retain their family character, the divided property loses all unity and becomes simply part of the separate estates of the various inheritors. It may still be regarded as the duty of the richer members of the family to help maintain the poorer; but this becomes a purely social duty, unconnected with the conception of a family estate charged with the maintenance of all the members. Only in the case of landed estates does this notion retain any force in developed industrial societies and even there it has been greatly undermined. In peasant societies, on the other hand, the idea of the family holding as charged with the family maintenance still retains great force. Often most of the family are driven or impelled to go away and work elsewhere, as factory hands or laborers or in a higher stratum of society as doctors, civil servants or lawyers. But even when they have left the family property, the notion of its responsibility for helping them in adversity survives with almost undiminished force.

In modern industrialized societies, where the conception of property has become highly individual and the family survives as a social rather than an economic institution, the tendency has been to leave inheritance as free as possible from regulation by the state and therefore to extend continuously the right of unfettered bequest. The state has still to postulate what is to happen in cases of intestacy, but with the increase of the will making habit, fostered both by the growth of education and by the enlarged freedom of bequest, intestacy becomes of less practical importance. Most people with anything considerable to leave do dispose of their property by will, and in most English speaking countries they are left a very wide discretion—practically complete freedom—to carry out their wishes.

In the early nineteenth century, in England at any rate, freedom of bequest came to be widely regarded as an integral part of *laissez faire*. The classical economists, especially McCulloch, argued strongly against the legitim and in favor of primogeniture as a social institution, on the double ground that division of property operated against its efficient exploitation and that the disinheriting of younger children gave them the maximum incentive to make their own way in the world. A secure competence they regarded as disastrous both for society and for the indi-

vidual who enjoyed it; and they urged that men would be spurred on to make the best use of their powers only by need and by emulation of the rich. Inequality was defended as a means to the accumulation of capital and primogeniture favored on the ground that although it might be bad for the heir by making him lazy it was good for the younger children and the community. According to McCulloch it was a positive privilege to be disinherited; but it never entered his head that the best thing would be to disinherit everybody.

Although primogeniture was favored, there was no desire to enforce it by law; for freedom of disposition by will was regarded as a necessary incentive to the accumulation of capital and it was intended that the father should be able to leave his property away from his children, thus having the whip hand over them while he lived and the authority to induce in them virtuous and industrious habits. The object was to give men the greatest possible incentive not only to make but also to save money; and this would be best secured by putting what they made and saved absolutely at their free disposal. Despite Jeremy Bentham's pleas for limitation of inheritance the nineteenth century doctrine of property and inheritance developed in England on purely individual lines in strict keeping with the philosophy of *laissez faire*. In this field as in many others it was left for John Stuart Mill to go back on the classical tradition and to propose in addition to some restrictions on the right of bequest a severe limitation of the sum which any one individual would be allowed to inherit from any source. Mill is hesitant, for he is impressed with the undesirability of doing anything to check capital accumulation. But he also dislikes and desires to reduce inequality and his wish is at several points the forerunner of modern doctrines dealing with taxes on inheritance.

Before Mill the question of inheritance was considered, except by the socialists, almost solely in relation to the accumulation of capital and the efficient use of productive resources and hardly at all as a problem of social justice. In Mill the two points of view are in conflict; and from his time the question has always to be considered from both standpoints. On the one hand, inheritance and freedom of bequest are defended as necessary incentives to saving and as means to the more effective use of capital; for, given freedom of bequest, it is held that men will tend to leave their capital in such ways as to promote its effective use. On the other hand, in-

heritance is attacked as one of the greatest sources of social and economic inequality and proposals are made to limit or even to abolish it in order to secure a better distribution of income.

Abolition of inheritance, however, can hardly be urged as a self-contained and sufficient reform, for if property is to lapse to the state at its owner's death, and that is what abolition involves, the state will have either to make use of it for production under collective control or to let it out to the individuals who seem best qualified to use it. The former is the socialist solution; the latter has been urged by various small groups from time to time and is urged today by the followers of Rudolf Steiner. In either case the abolition of inheritance involves a radical change in the economic as well as the social system and especially new methods both of accumulating and of using capital. It would also involve, at any rate in the first generation, some restrictions on gifts *inter vivos*, such as a real enforcement of the legitim also demands; but whether such restrictions would remain necessary after the first generation would depend on the opportunities for fresh capital accumulation still left to the individual.

There can be no doubt that under any socialist system, even if it fell far short of communist thoroughness, the right of inheritance would be in practise very severely restricted, for with the instruments of production in the hands of the state the chief means and therewith also the need of private accumulation would be gone. The accumulation of capital would clearly become a collective function of society. Incomes would be distributed after subtracting the amounts needed for the provision of new capital equipment; and they would be meant for spending, not for saving. Inheritance would thus be restricted at most to things of use and could not include instruments of production, except during a period of transition. Probably even within these limits it would be further restricted by law, at any rate as long as any considerable inequalities of income existed; for with the development of social services the argument that a man needs to provide for his children would be progressively undermined. Probably the bequest of personal possessions up to a limited amount would be allowed; but inheritance in excess of this would be likely to disappear, not so much because it would have been deliberately stamped out, though this might be the case, as because the need and opportunity for it would alike have gone.

There has been a good deal of dispute among economists about the extent to which the inheritance of wealth is in modern societies the principal cause of inequality. Its influence is likely to be greater in older settled countries than in new countries still largely at a pioneering stage, since the older countries have already much larger masses of inherited wealth and usually greater opportunities for investing it securely so as to perpetuate its existence. Invested money, from which the owner simply draws a revenue without venturing it in risky undertakings, is in old settled countries largely self-perpetuating. There are losses of course and men do sink from class to class on occasion, but under ordinary conditions in such countries reasonable prudence secures the perpetuation of wealth once acquired.

In older countries also there are usually fewer opportunities for the rapid acquisition of wealth by those who start life without it. There are some of course, and there are plenty of chances for the rich to become richer. But the older and the more settled in its economic habits a country is, the more likely wealth is to go to those who have some already and the smaller is the proportion of men likely to rise from nothing to great fortunes.

There can then be no doubt that in the older settled societies inheritance is a very big factor indeed in causing economic inequality, although the whole question of the relation of inheritance to economic inequality demands a more thorough investigation than has as yet been made. It counts for a good deal not only in perpetuating large fortunes but also in giving those who inherit even quite small fortunes a very long economic start over those who do not.

In the newer countries the influence of inheritance is probably less decisive, both because the current accumulation of new capital bears a higher proportion to the amount of inherited wealth and because, conditions being less settled, there are more opportunities for a man to rise either by accumulating capital for himself out of profits or by being placed at the head of a big business on the score of ability alone. Such countries, however, as they grow in wealth rapidly accumulate heritable property and begin to develop a propertied class distinct in some degree from the class of successful business men. The United States has already a large class of this type, although inherited wealth still probably counts relatively for less in America than in either Great Britain or France.

In nearly all countries the proportion of those dying who have anything substantial to leave is very small indeed. In England and Wales, according to estimates made by Professor Henry Clay, before the World War only 15.6 percent of all persons possessing incomes of their own had a total capital wealth of over £100 and only 6.8 percent had more than £500. Even in 1920-21, when prices were very high, only 24.6 percent had £100 or over and less than 12.3 percent £500. In Prussia, according to Dr. King, only 14 percent had over 6000 marks in 1908.

Inheritance in any economically significant form is thus confined to a comparatively small section of the population. Nor can there be any doubt that in the main those who die leave most of their money to persons of the same social class as themselves. There are of course many small legacies to poor relatives, servants and employees, but apart from charitable bequests the bulk of property tends to pass to relatives occupying a similar social status to those from whom they inherit. This causes inheritance even on a basis of freedom of bequest to act as a powerful force in perpetuating inequalities in the distribution of wealth and income. Gifts and bequests to charities have indeed an opposite tendency, for they usually result in the distribution of increased incomes or services to the poorer sections of the population. But in no country, not even in the United States, is the amount of gifts and bequests for education and charity large enough seriously to affect the distribution of wealth in society as a whole. Comprehensive figures are unavailable on this point but, according to Wedgewood, less than 1 percent of the estates of French persons were bequeathed to public and charitable institutions in 1912 and 1913. In Great Britain the proportion is probably somewhat higher. It is fairly certain that in the United States a much larger percentage of the wealthy man's property goes through gifts *inter vivos* or bequests to philanthropic institutions than in England or on the continent, although in the United States such bequests now seem to be declining.

The inheritance of wealth lies then at the very roots of the class structure of modern communities. Class divisions would not necessarily disappear if it were abolished; for if the change stood alone, differences of wealth and income arising within the lifetime of the individual would still be enough to lead to wide differences in education and in equipment for money making. The rich parent could still give his children

a preferential start in life by expensive professional training or by setting them up in business for themselves. It is, however, inconceivable that the abolition of inheritance should stand alone. If it came about it would certainly be accompanied by increased public provision for higher education, which would undermine class monopolies in the professions, and by a restriction of opportunities for the application of private capital to business enterprise. Inheritance is by no means the only source of class divisions and great economic inequalities, but it is difficult to imagine their persistence in anything like their present forms without it. This is the case, however, primarily because of the other social changes which the abolition of inheritance connotes and only secondarily because of the direct effects of its abolition.

Short of abolition the rights of bequest and inheritance can of course be drastically restricted without the immediate necessity for any complete change of economic system. Mill's proposal to limit the amount that can be inherited instead of the amount that can be bequeathed has nowhere been acted upon; but one state after another has introduced some form of inheritance taxation and thus confiscated to the public purse some part of the fortunes of those who die with any considerable property. Such taxation has many forms in different countries; but it usually involves some degree of graduation according to the total value of the estate and also some discrimination according as the property is left to nearer or remoter relatives or to strangers. Although inheritance taxes are not chiefly a method of influencing freedom of bequest but rather a method of taxing big accumulations of wealth, they are not nearly considerable enough to have noticeable effects in reducing inequalities of wealth or income.

It is sometimes suggested that this failure to reduce inequality by taxation of inheritance is in itself a sign that most big fortunes are made rather than inherited and that inheritance is not so powerful a factor as has been supposed in causing inequality of income. But this suggestion ignores the great power of large fortunes to attract more money. If it were not for death duties, the distribution of income in Great Britain would be still more unequal than it actually is. What is left of such fortunes after taxation, however, is ample enough to serve as a preferential basis for the accumulation of further wealth. It is not denied that in Great Britain, unlike the United States, economic inequality

has been somewhat diminished of late years; but this is a result far more of the heavier taxes on incomes than of the taxation of inheritance.

It is in effect impossible to divide the wealth of the richer classes into two parts, the one inherited or the result of those gifts *inter vivos* which are really a form of inheritance, and the other acquired by the owners' personal exertions; for this is to ignore the truth that money breeds money and that it is far easier for a man who inherits money both to make more and to save out of his income than it is for one who starts with nothing. Fresh capital accumulations are in part the result of saving out of inherited fortunes, and the invested capital on which large profits are made is in part inherited money. What a man makes in his own lifetime may be fully as much a result of his inheritance as of his personal skill, luck or exertion. It is therefore a sheer impossibility to isolate in any quantitative sense the results of inheritance, but it is fully possible to say that income and property would be very differently distributed if everyone started with an equal supply of capital.

However great the social and economic influence of inheritance is admitted to be, the institution will not lack defenders as long as it is considered necessary for the accumulation of capital. It is true that the growing tendency for industries to finance their own expansion out of reserved profits has led to some substitution of group for individual saving and has thus to some extent lessened the need for private accumulation out of incomes; and it may be that this method of group saving foreshadows a time when industry will be wholly self-financed or, at any rate, when the calls for capital out of individual savings will be much reduced. But for the present individual investment continues to play a large part in financing production and it is therefore deemed necessary to keep up the rate of saving. Some economists, notably J. A. Hobson, have suggested that in prosperous times capitalist societies attempt to save and invest too large a proportion of their incomes, which results in a deficiency in the demand for consumers' goods. There is much to be said for this view, which would provide an economic justification for measures tending to reduce the volume of saving in prosperous times, including the higher taxation of inheritance at such times and the appropriation of the proceeds as revenue and not as capital. It cannot be held, however, that this tendency to oversaving exists, in the same degree at any rate, when times are bad; while it

is precisely at such times that the state, hard pressed for revenue, is likeliest to use capital taxes for meeting current expenditure.

In any case the need for private accumulation of capital does still exist in a considerable degree in modern societies and inheritance will continue to find defenders on the ground that it promotes this end. It will indeed be defended not so much in spite of its tendency to aggravate inequalities of wealth and income as because of this tendency; for there is a school of economists that maintains that the richer the rich are, the richer will the poor be also, because the highest production and the highest wages will be secured when profits are highest and profits will tend to be highest where the accumulation of capital has been pushed to the furthest point. This view has of course some plausibility; admittedly inequalities of wealth and income are greatest in the richest societies and these have also the highest real wages. But it does not follow that the high productivity on which this wealth is based is the product of economic inequality or that unrestricted inheritance is necessary to its maintenance.

Admitted, however, that any severe restriction on the right of inheritance would, unless the state used the proceeds as capital, reduce the rate of capital accumulation; the question is how far severer taxation of inheritance would react on the individual's will to accumulate.

That high inheritance taxation stimulates gifts *inter vivos* is evident enough. That it does not have this effect in a far greater measure is a clear sign of the tenacity with which the aging tend to cling to their money. Most of them remain unwilling to surrender ownership or control to their children, except on a small scale, despite the possibility of avoiding a good deal of taxation. This bears out the point that in general the psychological incidence of taxation is upon the inheritor and not on the testator.

If this is so, it seems reasonable to suppose that taxes on inheritance will not much affect the will to save. It is moreover highly relevant to point out that among the richest members of a community saving is largely automatic in that it represents surplus income beyond the desire to spend. Clearly saving of this sort will not be affected by taxation except to the extent to which gifts *inter vivos* and charitable donations may be stimulated. Graduated taxes on large incomes by reducing automatic saving react far more decisively on the volume of accumulation than do death duties.

In the case of small fortunes taxes on inheritance where they exist at all are usually at a low rate and unlikely to affect saving, although they may to some extent direct it to forms of saving that are exempt from the tax, such as life insurance policies.

If a state should, however, merely by gradually increasing its taxes on inheritance seek to abolish inheritance altogether, it would reach a point, far short of actual abolition, at which the taxation would react sharply on the volume of saving. Accordingly any state pursuing such a policy would have to take steps in the course of it to bring into being alternative methods of capital accumulation on a collective basis and would have to apply the product of its inheritance taxes as capital and not as income.

Plans for the abolition of inheritance are necessarily anticapitalistic; for they involve either direct collective operation of capital resources or collective control and rationing of their use. They are not necessarily socialist but they do imply the supersession of capitalism as an economic system. It is not possible to advocate the abolition of inheritance on purely ethical grounds without being prepared to suggest alternative methods for the accumulation of capital; and to this difficulty socialism presents the most obvious answer. Moreover if inheritance is abolished or even if taxation of it is pushed very far, it becomes inevitable for the state as the taxing authority to take over actual assets, since beyond a certain point the proceeds of inheritance taxes could not possibly be collected in money. The state then would become in effect the heir and it would be difficult to avoid the conclusion that the state should administer the assets acquired by way of taxation.

The economic and the ethical aspects of the question are thus closely intertwined. Many persons who are not prepared to defend inheritance directly on ethical grounds nevertheless uphold its economic desirability, because they mistrust the effects on production of an approach to socialism, and are ready to advocate the taxation of inheritance up to the point at which they think it will interfere with the private accumulation of capital. This was in essence Bentham's position and it has still powerful upholders in the world today.

To others the ethical arguments, which are directed partly against inequality in general and partly against inequalities resulting from inheritance and not from a man's own exertions, constitute a strong inducement to consider

favorably any economic system which will make these inequalities unnecessary. The case for socialism, which is based on a mingling of economic and ethical considerations, gains here a powerful reenforcement; for it can be pointed out that what the legatee in fact inherits is not a sum of money but essentially a claim on the productive capacity of society. This capacity, the result of centuries of development, is in reality a social product, the common heritage of civilization, in which it would seem that all are entitled to share. In other words, when a man saves under present conditions, the result is to secure to him much more than he saves because he acquires a preferential share in the social heritage. It seems unfair that a man should be able to pass on this preferential claim to his successors without limit. Most states have passed legislation to prevent "perpetuities" and to limit testators' rights to prescribe for generations ahead how their money is to be used or to order that it shall accumulate at compound interest for a long period. But in spite of these restrictions there is nothing to prevent the claim itself from being perpetual; this seems to many people to be manifestly unjust.

It is true that capital does not in most cases survive forever in an unbroken line of succession. Physical instruments of production, except land, wear out; and even where the capital they represent is perpetuated by the provision of adequate allowance for depreciation, there are hazards which do in the long run bring the life of most forms of business enterprise to an end. Even states though they cannot go bankrupt do sometimes repudiate their debts and so confiscate the property of their bondholders; and apart from the wasting of the assets themselves there is likely at some point in a long succession of heirs to arise a wastrel who will dissipate his patrimony. But with the growth of trust companies and the corporate organization of business this becomes increasingly a less important factor. It is indeed often stated that the life of most inherited fortunes is not long except in the case of landed estates; and this is probably true if it is meant that large fortunes are seldom kept together for many lives in the hands of a succession of sole heirs. There is a trend toward division of fortunes as well as to wastage; and this tends to become more pronounced as property can be more and more easily divided through the operation of the joint stock system. But property rights are not any the less perpetuated because they are divided up; the division

does not make strongly for greater equality, because the property even if it is divided is usually left in the main to persons of the same social class.

It is possible to imagine a form of socialism or, at any rate, collectivism that would perpetuate inheritance much in its present form. If the state carried on industry, borrowing the money from its citizens as it borrows now in the case of nationalized or municipalized undertakings, inheritance could continue, the inherited property taking the form of perpetual state bonds or stocks. It is, however, difficult to imagine such a system being of long continuance, for it would clearly render the private owners of the capital completely functionless, mere receivers of interest or dividends with no claim to income based even on a show of service. Under such conditions they would certainly before long suffer expropriation, for no economic or social institution can survive permanently if it has lost the function which it came into being to perform. Socialism of this type would end, although it had not begun, in the abolition of inheritance or in its restriction to things other than claims arising out of loans to the state.

Belief or disbelief in the institution of inheritance is therefore very closely linked up with belief or disbelief in the private ownership and operation of the instruments of production. The abolition of inheritance or its limitation to personal possessions of use is in practise if not necessarily in theory a socialist doctrine. Peculiar interest therefore attaches to the handling of the problem in Soviet Russia, where almost the first step of the new government in 1918 was to decree the abolition of inheritance of all property above 10,000 rubles except for provision for meeting claims of relatives based on proved need. This attitude has since been modified and under a decree of 1922, the civil code (1923) and a decree of 1926 the limitation on the value of the property which can be inherited is removed; direct descendants, dependents and surviving spouses are entitled to share; and furniture and household effects go to the housemates of the deceased. Wills can be made so as to vary the disposal of property among the legal heirs but not so as to leave it to others; and in the absence of testamentary provision distribution among those entitled to benefit is equal.

The new provisions mean far less than appears on the surface since they are indeed rather the result of the Communists' success in destroying private property than any token of a reversal of

ideas or policy. The Soviet government can now afford to permit inheritance because it does not permit the accumulation of wealth in private hands and because, when accumulation does exceptionally still occur, it has plenty of other methods besides the prevention of inheritance of breaking it up. The private trader or the *kulak* (rich peasant) who succeeds in amassing property has no security at all of being able to retain it for his own lifetime; and the question of his right to pass it on to his descendants therefore loses most of its importance. The one form of private property which has hitherto remained in being is now on the road to destruction by the placing of agriculture on a collective basis; and when that has been completed, the citizens of the Soviet Union will have only personal possessions to leave, except for the continuance for the time being of a small quantity of state bonds. For the Soviet Union does still to a small extent supplement the collective supply of capital by borrowing from its citizens.

This shows that, when a transition from capitalism to socialism is made abruptly and is accompanied by a general confiscation of existing wealth, the question of inheritance ceases at once to possess much economic importance; for both the existing capital and the power of fresh private accumulation are taken away at a blow. Moreover while private accumulation may survive for a time it is more likely to be attacked by the direct confiscation of property from living owners than by the removal of the right of bequest or inheritance.

Inheritance as a contemporary problem is therefore essentially a problem of capitalist society; and it cannot be abolished or restricted within narrow limits so as still to leave capitalist society intact. If private persons are not to inherit, the state must; and state inheritance means state control of the use of capital. Propaganda for the abolition of inheritance is in most cases in effect propaganda for socialism; and the question of inheritance, as distinct from taxation of it within limits that will not destroy its essential character, thus merges in the wider question of a socialist versus a capitalist framework of society. This is why there has never been any important social or economic movement making the abolition of inheritance its main objective.

If it is impossible to abolish inheritance without altering profoundly the economic structure of society, it is no less out of the question to retain inheritance in anything like its present form if that structure is radically altered in a socialist

sense. For inheritance is bound up with the division of society into distinct social and economic classes and influences this division the more profoundly because in advanced communities the better off classes tend to have lower birth rates than the poorer sections of the people and therefore to keep their wealth within a narrow range. The institution of inheritance helps indeed to foster this control of numbers among the well to do, since they are conscious of the need for limitation as a means of preserving their class status. Even where primogeniture remains the custom this limiting influence holds good; for the disinherited younger children are likely to be provided for during the testator's life by expenditure on education and training, by enabling them to start in business or by marrying daughters off with at least some "portion" of their own. It is true that the growth of feminism has tended to cause further diffusion of property, for daughters are now more often than before treated on an equality with sons. But this may even accentuate the tendency toward family limitation among the middle class.

The future of inheritance then appears to depend, on the one hand, on the growth in modern communities of collective methods of capital accumulation and of the control of business resources and, on the other, on the pressure of the popular movement toward a less unequal distribution of incomes; for this movement, ethical as well as economic in its driving force, results in forms of taxation which limit saving and impinge on profits and thus leads to the necessity of alternative methods of saving and of insuring adequate production. The two influences thus meet and mingle; and it is not easy to see how the institution of inheritance, save in a greatly modified form, can indefinitely stand out against them, despite the fact that it is for the moment strong.

To the extent to which it is restricted there is a return from the individualistic notion of property to a communal notion, based now on a unit wider not only than the family but also than the clan or tribe, since property comes to be regarded as part of the social heritage of the modern community, legitimately charged with the maintenance of all its members. This notion may further undermine, as it has already undermined in Soviet Russia, what remains in industrial societies of the conception of family solidarity. It will inevitably affect the institution of marriage and the relations between parents and children. But even in capitalist society the family

has largely lost its economic significance and become, save in respect of inheritance, mainly a social unit whose bonds have grown far looser even within living memory. If inheritance goes, the last economic bond will be snapped, at any rate beyond the period of the children's upbringing; and that too is likely to become increasingly a social function.

INHERITANCE TAXATION. The inheritance tax is a levy made on the occasion of the transfer of property at or in connection with the death of the owner. It may take the form of a tax on the estate as a whole, on the respective shares of the beneficiaries or on both. The tax is variously held to be a direct tax upon property (of testator or recipient) or an indirect tax upon the act of the transfer or receipt of property at the death of the owner. In modern times the inheritance tax has been incorporated into the tax system of every important country.

Transfers of property at the death of the owner were subject to the property transfer taxes of ancient Egypt and Greece. The element of death, however, was purely incidental in these taxes. The first true inheritance tax was the Roman *vicesima hereditatium* instituted in 6 A.D., a 5 percent tax on collateral inheritance and bequest. With various modifications this tax persisted for several centuries.

During the Middle Ages there were certain feudal dues—the relief, the *Erbkauf* and the heriot—which resembled inheritance taxes; in several countries the royal relief evolved into a rudimentary national inheritance tax. By the end of the fourteenth century several forms of death tax had been established in the Italian and German commercial cities. The seventeenth century

saw the enactment of inheritance taxes in the Dutch provinces and in a number of German principalities. By the end of the seventeenth century there were inheritance taxes in the four national states, England, France, Spain and Portugal.

The substantial development of the European inheritance tax occurred during the nineteenth century. From a disorganized set of minor probate duties the English tax expanded into a full fledged estate duty; it was extended from personalty to real property; its rate schedule, at first regressive, became proportional and then progressive. The present English estate duty is supplemented by the legacy duty on movable property and the succession duty on immovable property; both taxes, levied on the shares received by the individual beneficiaries, are graduated according to the degree of the beneficiary's relationship to the deceased. The French inheritance tax, established in 1796, had rates graduated according to the relationship of the beneficiary or heir to the deceased and discriminated between realty and personalty; during the nineteenth century the discrimination according to the character of the property was eliminated and the relationship graduation was augmented; in 1901 the rates of the tax were made progressive. Italy in 1862 adopted an inheritance tax modeled on the French law; its rates were made progressive in 1902. The Prussian collateral inheritance tax of 1873 was followed by similar taxes in the other German states; growing agitation for an imperial inheritance tax resulted in 1906 in a national inheritance tax with relationship discrimination and progressive rates.

The general character of European inheritance taxes has undergone no radical change during the past twenty-five years. During the World War and the post-war years because of the pressure of increasing fiscal burdens and the growing political power of propertyless groups rates increased and progression was sharpened; since 1921 in France combined maximum rates of estate and inheritance taxes would call for a rate of 98 percent, were not the maximum limited by law to 80 percent. Various discriminations have been experimented with to bring these heavy taxes more in line with various concepts of fiscal justice. During recent years inheritance taxes have yielded over 10 percent of the national tax revenue in England, over 5 percent in France and less than 1 percent in Germany.

A dozen American states attempted the levy of

inheritance taxes during the first three quarters of the nineteenth century, but their statutes were badly drawn and poorly administered and most of these early state taxes were repealed within a few years of their levy. Effective use of the inheritance tax did not occur in the United States until the New York inheritance tax law of 1885, carefully drawn and well administered, proved a success. Other states were encouraged to experiment with this form of taxation, and by 1902 twenty-six states levied inheritance taxes of one sort or another. The taxes of this period were all proportional, usually embodied relationship graduation and were generally limited to collateral inheritance and bequest. In 1892 New York led the way to extending the tax to direct heirs. Wisconsin in 1903 enacted a progressive inheritance tax which soon became the model for other states.

In the years 1797 to 1802 the federal government collected a stamp tax on successions by inheritance to personal property. A federal inheritance tax was also levied during the Civil War decade. The inheritance tax embodied in the federal income tax act of 1894 was abandoned when that income tax was declared unconstitutional. Four years later a short lived progressive tax was levied as part of the Spanish War tax program. Not until 1916 did the federal government make an inheritance tax a permanent part of its tax system. The tax levied in this year was an estate duty applying to estates in excess of \$50,000 with a progressive rate schedule rising to a maximum of 10 percent on the excess of an estate over \$5,000,000. Subsequent revenue acts increased the rates of this tax until in 1924 the rate on the excess of an estate over \$10,000,000 was 40 percent. The maximum rate was reduced to 20 percent in 1926, but was raised to 45 in the revenue act of 1932.

A feature of the 1924 federal estate duty was the allowance of a credit to taxed estates to cover state inheritance taxes charged against them; the maximum credit allowance was 25 percent. When the rates of the federal tax were lowered in 1926, this credit was increased so that it ranged from 15 to 75 percent; this credit schedule was maintained in 1932 when the estate duty was raised. The effect of this credit was to eliminate the burden of state taxes on estates where the rates of the state taxes did not exceed the credit allowed under the federal tax. State inheritance taxes were thus deprived of their effect of driving rich individuals to adopt residences in states levying no or low inheritance

taxes. The consequence of this federal estate tax credit was an increase in the number of states levying death taxes; in 1932 only Nevada was without an inheritance tax. The rates of the state taxes were generally increased so as to take full advantage of the credit; in the process many states changed the form of their taxes from inheritance taxes levied on the shares received by the beneficiaries to estate taxes levied on the full estate left by the decedent, so as to obtain an exact adjustment of the rates of their inheritance taxes to the credit allowed under the federal estate duty.

Because of the large initial exemption of \$100,000 and the generous credit allowance to cover state inheritance taxes the federal government received little revenue from its estate duty in 1926-32. For fiscal year 1929-30 its receipts from this source were \$64,842,725, less than 2 percent of its total tax revenue. State governments during their 1929 fiscal years derived \$148,591,827, about 9 percent of their total tax revenue, from their inheritance taxes.

There has been much dispute both in Europe and in America as to the legal character of the inheritance tax. One school of nineteenth century thought, stemming from Bentham, held that the inheritance tax can be viewed as an exercise of the state's inherent right to regulate inheritance and bequest. Another, developed by Münzinger and championed by Bluntschli, Wagner and Ely, held that the state as feudal overlord of the individual was coheir in every estate and took its share in the form of an inheritance tax. These two theories never gained wide acceptance, and the inheritance tax is now universally viewed simply as a tax levied under the state's taxing power.

Distributive justification of the inheritance tax has been based on many theories of tax justice. Moderate transfer fees have been defended as a recompense to the state for its supervision of the ownership of the property of a deceased person. Heavier inheritance taxes have been justified as a recompense for the protection accorded to property during the lifetime of its owner. The quid pro quo doctrines of tax justice, however, afford little encouragement for inheritance taxation, and appeal to them is generally made by the opponents rather than the supporters of inheritance taxation. The ability and sacrifice doctrines have been heavily drawn upon in defense of inheritance taxation, particularly of progressive inheritance taxes. The deceased, it is argued, has no further use for his

property, while to the heirs and beneficiaries it is an unearned windfall whose reduction by a tax involves no sacrifice whatsoever. Several writers, like Graziani and Adams, have chosen to view inheritances or bequests as simple increments of income received by the beneficiary and so subject to all the ability and sacrifice doctrines applying to income. Seligman justifies the inheritance tax both as a tax on accidental income and as a payment for the privilege of inheritance conferred by the state.

Several unusual distributive justifications for inheritance taxes are to be noted. A scattered group of writers have defended this tax on the ground that it constitutes a lump sum payment of taxes evaded by the deceased and his estate during the lifetime of the deceased or a lump sum payment of periodic taxes, such as the income tax, not conveniently levied in their true form. Certain American writers have viewed the state as a silent partner in the accumulation of individual fortunes and have described the inheritance tax as a method employed by the state to realize on its partnership share. Individual radical writers have urged inheritance taxes as a method of breaking down large family fortunes and so reducing inequality in the distribution of wealth, although the socialist school of writers have generally ignored the inheritance tax, viewing it as merely an undesirable palliative of the evils they are attacking.

The levy of inheritance taxes has raised many practical issues which have not yet achieved final solution. There still exists open disagreement as to the respective advantages of the inheritance tax levied on the shares of an estate received by individual beneficiaries and heirs and of the estate tax levied on the entire estate left by the deceased. The latter is the form of the English estate duty and of the American federal estate tax, while the former is employed on the continent and was until recently the characteristic form of American state inheritance taxes. The great advantage of the estate tax is the simplicity of its determination: only one calculation is involved for each estate and there are no complications caused by life estates, remainders and contingencies. Furthermore a progressive estate duty with a given schedule of rates has a higher yield than an inheritance tax with the same schedule of rates; the fractions of an estate received by the individual beneficiaries and heirs rarely involve the application of the same high bracket rates to which the undivided estate would be subject. The disadvantage of the estate

tax is its maladaptation to the ability and sacrifice doctrines of tax justice. Only by strained reasoning can the ability and sacrifice theories be made to support the use of progressive rate schedules in an estate tax. Furthermore an estate tax is not adapted to relationship graduation; where such graduation is effected in an estate tax, as in the Canadian provincial death duties, it is at the cost of simplicity and facility of administration.

Relationship discrimination is itself an open issue in inheritance taxation. Its strongest theoretical foundation is the family sense, the feeling that the direct heirs of a deceased person have a greater claim on his property than collateral or unrelated beneficiaries, that the former are but realizing a latent property right in the estate while to the latter their shares are pure windfalls. Some writers, like Scheel and Puviani, have attempted to make out a case for relationship graduation on the basis of the sacrifice doctrine of taxation; they argue that the value of the property coming to direct heirs is lessened by their grief over the death of the decedent, that this diminution of the value of an inheritance decreases with the distance of the relationship between beneficiary and deceased and that the relationship graduation of an inheritance tax offsets this "grief sacrifice." In the Latin countries, where the sense of family remains strong, relationship graduation in death taxation is carried out to minute detail. In the English speaking countries, on the contrary, the trend seems strongly against such graduation, except for generous rate and exemption allowances to the widow and children of the deceased, who in gaining an inheritance have lost their breadwinner.

Progressive inheritance taxes, as previously indicated, do not derive much support from the ability doctrines of taxation. If the tax be viewed as one on the property owned by the decedent, it is difficult to see wherein the ability doctrines can apply to a dead man. If the tax is considered a levy on the recipients of the estate, their tax-paying ability is determined not only by the shares of the estate received by them but also by the property owned by them; surely a rich man receiving a small inheritance has a greater tax-paying ability than a poor man receiving a large inheritance. These considerations prompted several German writers to advocate the graduation of the tax rates on the basis of prior wealth of the heir plus his inheritance. The German and Italian inheritance taxes of 1919 made pro-

vision for supplementary graduation of the tax rates according to the prior wealth of the heir. Effective determination of such prior wealth proved administratively impracticable, however, and in both Germany and Italy this provision was abolished in 1923.

Beginning with Adam Smith fiscal economists have pointed out an important discrimination in the inheritance tax; namely, that it bears unequally upon the property of families according to whether deaths in the family follow each other at short intervals or are widely spaced. With the heavy rates now in effect in some countries a rapid succession of deaths in a family could easily wipe out a large family property. Various proposals that the tax on an estate be proportioned to the number of years it had been enjoyed by the deceased have never been embodied in legislation. Instead, beginning with the Chilean inheritance tax of 1878, many taxes have included a provision for a rebate of the tax on any part of an estate which has paid an inheritance tax within a period of preceding years, usually five. Such a provision is found in the American federal estate tax and in the inheritance taxes of fifteen states.

Several of the European inheritance taxes involve a rate discrimination intended to favor decedents or beneficiaries with large families. In France the inheritance tax of 1917 allowed a beneficiary a 10-percent reduction in his tax for each child above the number of three. At the same time a progressive estate duty called the *taxe successorale* was levied on the estates of decedents who died leaving fewer than four children; besides progression based on the size of the estate the rate schedule of this tax was graduated in accordance with the number of the children left by the deceased; the rates on the estate of a deceased leaving three children ranged from $\frac{1}{4}$ percent to 3 percent, while those on the estate of a childless decedent ranged from 2 percent to 24 percent. The Belgian tax of 1919 provided for a 2-percent reduction of the tax on a beneficiary for each of his children. It is doubtful whether such fiscal discriminations can have any effect on the birth rate of a country. Rather they provide an excuse for the levy of tax rates higher than might otherwise be acceptable to the popular temper of the times. The favoring of a beneficiary or heir with a large family finds ample justification under the ability doctrines of taxation, since it can logically be argued that the expense of maintaining his large family definitely reduces his taxpaying ability; the levy of special rates on

the estates of decedents with few or no children, as under the *taxe successorale*, does not enjoy such support in ethical theory.

Soldiers and sailors who die while in the national service are sometimes favored under inheritance taxes. The English death duties have accorded full or partial exemption to such decedents since 1694. Exemption to the estates of officers and men who fell in the World War was introduced into the French and American death taxes.

Certain minor discriminations found in earlier inheritance taxes are no longer common. The seventeenth century inheritance taxes of the Dutch provinces and some of the inheritance taxes of the Canadian provinces and of the American states levied discriminatory rates on bequests to or inheritance by alien heirs. The only defense for such discriminations is a rather narrow nationalism, and in most cases they have been rendered inoperative by international treaties of fiscal reciprocity. Another outworn mode of discrimination is the levy of special high rates on the transfer of property by intestate succession. Such discrimination was found in the early death duties of England, Sweden, Uruguay and Brazil. It probably represented a belated aftermath of the mediaeval ecclesiastical prejudice against intestacy and it no longer has a place in inheritance tax legislation. A third special discrimination peculiar to the inheritance taxes of the American states was the levy of penal rates on such part of an estate as had evaded other state taxes during the lifetime of the deceased. Such a provision appeared in the Wisconsin tax of 1899, the Louisiana tax of 1904, the New York tax of 1917 and the Connecticut tax of 1918. In every case the penal tax proved administratively impracticable and was soon dropped.

A unique proposal by the Italian economist Rignano has recently received much favorable attention. His suggestion was to levy a supplementary estate tax on such part of an estate as had been received by the deceased as gift, inheritance or bequest during his lifetime, that is, on the property which had not been accumulated by him through his own efforts. Rignano's underlying idea was frankly socio-ethical rather than fiscal. His proposed tax would result in breaking down large fortunes by striking at their root—the transfer intact from generation to generation of large family properties; levied with the high rates advocated by Rignano, such a tax would provide a "painless transition to socialism." In the more moderate form suggested by

its American and English proponents it would be less of a weapon of social revolution and more of a fiscal expedient. To date no inheritance tax law has embodied the proposal.

The history of death tax legislation shows a steady broadening of the scope of the statutes to block possibilities of evading the tax. Fictitious debts created in favor of beneficiaries, joint estates passing by survivorship, testamentary trusts, provision for excessive remuneration to executor beneficiaries, deathbed donations and gifts made prior to and in anticipation of death have all been brought within the scope of death tax statutes. Only the last named class of transfers still presents a problem to the death tax administrator. The federal and state inheritance tax laws in the United States have sought to circumvent this form of evasion by providing that gifts made "in contemplation of death" shall be taxed as part of the estate transferred at death. At first the statutes set specific periods, ranging from six months to six years prior to death, within which time gifts made by a property owner would be deemed attempts to avoid the inheritance tax and should therefore be taxable as part of the estate. The American courts have shattered this arbitrary attack, and at present the most that tax administrators can claim with regard to such gifts is the presumption that they were made in anticipation of death. A more direct approach to this problem is the levy of a gift tax as a supplement to an inheritance tax. All gifts except deathbed donations are subject to such a gift tax irrespective of whether they are made to avoid the inheritance tax or are innocent of ulterior motive. Gift taxes of this nature are common in Europe. The American federal government levied such a tax in 1924, abolished it two years later and enacted another gift tax in 1932, with a rate schedule ranging from $\frac{1}{2}$ percent to $33\frac{1}{3}$ percent.

Outright evasion of an inheritance tax is difficult if the tax is administered with reasonable effectiveness. Administration of the early American state inheritance taxes was usually left to the probate courts, charged with supervision of the administration of estates. The indifference of the officers of these courts to the fiscal duties arbitrarily imposed upon them led to the failure of these early state inheritance taxes. When administration of the tax was transferred to central state agencies, evasion of the tax was readily checked. Administration of inheritance taxes in the United States and England is facilitated by the circumstance that the executor or adminis-

trator of an estate who is charged with payment of the tax is an officer of the probate court which appoints him and is accountable to the court for his actions. The opportunities for successful evasion of the tax are so slight and the penalties which would be incurred by such abuse of the executor's or administrator's official obligations are so heavy that there is little incentive to tax evasion. In the continental countries, where control over the administration of estates is not so effective, the fiscal authorities rely to a greater extent on minute and inquisitorial examination into the lifetime transactions of the deceased.

It is generally accepted that the inheritance tax is not shifted. It reduces the shares of estates received by beneficiaries and heirs, and it is beyond their power to pass their tax burden to other economic classes.

It is frequently argued that an inheritance tax is injurious to economic development because it destroys capital, diverts it from productive uses and discourages the incentive for saving, thus acting as a deterrent to accumulation of capital.

The first argument, sponsored by Ricardo, is based on the assumption that a tax "measured" by capital is necessarily paid out of capital property. This, however, is not the case. Fixed capital remains unimpaired regardless of the tax on it at the death of the owner. It is true that the payment of a high inheritance tax which is in the nature of a sudden liability may result in forced liquidation and consequent depreciation of assets. But the loss here is purely individual. What is lost by the seller is gained by the buyer. From the social aspect the economic significance of the property remains unimpaired. Furthermore the various provisions for the distribution of the tax over a number of years, in England as many as eight, and the growing practise of providing for the payment of the tax through insurance obviate the necessity for forced and hasty liquidation.

With regard to the effect of inheritance on the volume of liquid capital available for investment it must first be determined whether the high tax rates on inheritance are offset by reductions in other taxes and if so whether the reductions apply to that portion of wealth which is likely to be saved, that is, turned into capital, or to the part of wealth which is likely to be diverted to the purchase of consumers' goods. In the former case the loss in the volume of saving occasioned by the payment of the inheritance tax will be offset by the greater saving capacity of other taxpayers. In the latter case, which is more frequent in democratic countries, where the reductions
